c = focal length of the collimator of the spectroscope—that is, of the lens c in Fig. 2.

F' = focal length of the object-glass of the spectroscope-telescope—that is, of the lens e in Fig. 2.

f = focal length of the eye-piece of the spectroscope-telescope—that is, of the lens g in Fig. 2.

If the image formed at f were of exactly the same size as that formed at b, the magnifying power would evidently be equal to $\frac{F}{f}$; and the actual magnifying power will be greater or less than $\frac{F}{f}$, according as the image at f is larger or smaller than that at b. As the beam of light is supposed to contain rays of only a single wave length, the prism d can produce no effect upon it except that of bending it out of a straight path, and the size of the image at b must be to the size of the image at f as the focal length of the lens c is to the focal length of the lens e. The required formula will therefore be

$$m = \frac{F}{f} \times \frac{F'}{c}$$

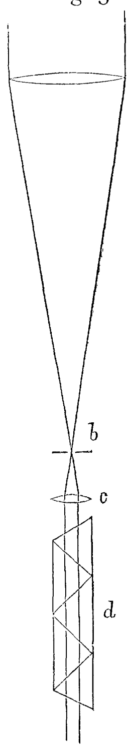
As it is desirable to avoid using the measured focal lengths of lenses whenever possible, this formula may be written

$$m = \frac{F}{c} \times \frac{F'}{f}$$

where $\frac{F'}{f}$ is the magnifying power of the spectroscope-telescope—a quantity which can be at once determined by means of a Ramsden's dynameter. Applying this formula to the case of the spectroscope, whose optical constants are given above, used in connection with the telescope of 43.58 inches focus, we find

$$m = \frac{43.58}{6.52} \times 5.71 = 38$$

Fig. 3.



If, instead of an ordinary spectroscope, one of Mr. Browning's small direct-vision instruments is employed, the formula given above will require to be somewhat modified. The optical arrangement will then be that shown in Fig. 3. The light falling on the object-glass *a* will be brought to a focus at *b*, and will there form an image between the jaws of the slit situated at that point. Then, passing through the lens *c*, whose principal focus is at *b*, the rays composing the beam will be rendered parallel, and after traversing the direct-vision prism *d* they will be viewed by the eye of the observer. Adopting the same notation as before, in this case we shall evidently have

$$m = \frac{F}{c}$$

An Arago Polariscope of double rotation, consisting of a brass tube 1.07 inches in diameter and 9.4 inches long, one end of which contains two plates of quartz, each cut perpendicularly to the axis, of the same thickness, and standing side by side, but one of them possessing right-handed rotation, the other left-handed rotation. The other end of the tube contains a double-image prism, and a convex lens of 9.0 inches focal length, which produces distinct vision of the compound plate of quartz to an eye placed at the double-image prism. This instrument gives images of complementary colors when polarized light is present.

An Arago Polariscope, consisting of a plate of selenite, and a double-image prism, giving images of complementary colors when polarized light is present. This instrument is fitted to one of the eye pieces of the 43-inch telescope.

A Savart Polariscope, consisting of a plate of quartz cut obliquely to the axis, and a plate of tourmaline, giving Savart's bands when polarized light is present. This instrument is also fitted to one of the eye pieces of the 43-inch telescope.

A Sextant, made by Stackpole & Brother, of New York, from my own designs, marked No. 937, of six inches radius, divided on platinum, and reading to ten seconds, having a telescope of 5.32 inches focus and 0.89 inch clear aperture, provided with eye-pieces magnifying respectively 2.75, 5.66, and 8.88 diameters. Attached to the index bar is a finding level, which saves much time and trouble in picking up the reflected image of an object.

Owing to my severe and protracted illness in Scotland, I have not had time to make any investigation of the error of eccentricity of this sextant since my return. In reducing the observations, I have therefore employed the errors determined in 1869, which are given in the following table; ω is the reading on the arc and E the corresponding correction for eccentricity.

ω	E	ω	E	ω	E
°	″	°	″	°	″
0	0.0	50	+ 8.1	100	+19.9
10	+ 1.2	60	10.2	110	22.6
20	2.6	70	12.5	120	25.3
30	4.3	80	14.9	130	28.0
40	+ 6.1	90	+17.4	140	+30.8

A Mercurial Artificial Horizon, marked Ha. 1, having a folding roof, and an iron trough three inches wide by five inches long. A very careful investigation of the errors of this horizon, made by reflecting the pole star from it, and observing the reflected image with the mural circle, showed that the maximum error which can be produced in the mean of a set of observed double altitudes by omitting to reverse the roof, is only 0″.24.

A Pocket Sextant, made by Stackpole & Brother, of New York, marked No. 346, having an arc of two and a quarter inches radius, and reading to single minutes.

A Black Glass Artificial Horizon, four inches long by three inches wide, provided with a very sensitive level and an inclined plane, with black glass surfaces, which can be set on the horizon for the purpose of measuring zenith distances ranging between seventy and one hundred and thirty degrees.

A Prismatic Compass, having colored glasses for the purpose of observing the sun, and a needle three inches long, carrying a metal circle three inches in diameter, divided to single degrees.

A Small Reflecting Level.

Two Pocket-Compasses.

A fifty-foot Chesterman's Metallic Tape-Measure, which had been carefully tested by a standard, and was found to be too long in the proportion of 100.134 to 100.000.

A Binocular Field-Glass, magnifying 5.50 diameters, and having a field of view of 2° 50′.

A Pocket Achromatic Telescope, having an object-glass made by Alvan Clark & Sons, of 9.99 inches focal length and 1.09 inches clear aperture, with a terrestrial eye-piece magnifying 19.2 diameters and a field of view of 1° 48′; provided with a screw clip for holding it steadily while observing.

A set of three Colored Glasses, mounted in a german-silver frame, for the pocket.

A Pocket Aneroid Barometer, 1.9 inches in diameter, made by L. Casella, of London, and marked No. 1128. It has a scale extending from 23 to 31 inches, graduated to 0.05 of an inch, and is compensated for temperature.

Two Pocket Thermometers.

A Rain Gauge, having a receiving surface 2.788 inches in diameter, and a glass measure for the same, holding fifty cubic centimeters and graduated to half a cubic centimeter—each half cubic centimeter being equal to 0.005 of an inch of rain.

A set of Drawing Instruments.

We had with us, for the use of the party, four excellent mean time box chronometers, made by T. S. & J. D. Negus, of New York. They were marked numbers 1115, 1228, 1256, and 1340.

I had also a number of books and other articles, a full list of which is given in Addendum C to this report.

IV.—PROBABLE ERROR OF OBSERVATIONS MADE WITH A SEXTANT.

As the sextant is a very portable and convenient instrument, and is much used for scientific purposes, it seems worth while to determine carefully what degree of accuracy may be expected in observations made with it. For that purpose I have collected in the following table nearly all the data which can be derived from the work of the officers of this Observatory in connection with the total solar eclipses of August, 1869, and December, 1870. It is to be understood that each set of altitudes consists of six readings, the object being observed in a mercurial artificial horizon, with a sextant whose telescope magnifies about nine diameters, and whose vernier reads to ten seconds; and further, that with each set of six altitudes, the index correction has been determined by six readings made for that purpose.

TABLE I.

Observer.	Station.	Object of Observations.	Object Observed.	No. of sets of Altitudes.	Probable Error of Time.	Probable Error of Altitude.
					s.	″
Harkness . .	Des Moines. . .	Latitude .	Sun . .	16		±3.89

Hall	Syracuse and Malta	Latitude .	Sun . .	11		3.12
Harkness . .	Des Moines. . .	Time . .	Sun . .	20	±0.145	1.63
Harkness . .	Syracuse. . . .	Time . .	Sun . .	38	.321	2.59
Hall	Syracuse and Malta	Time . .	Sun . .	40	.381	3.05
Harkness . .	Des Moines. . .	Latitude .	Polaris .	3		6.85
Harkness . .	Syracuse. . . .	Latitude .	Polaris .	6		8.29
Hall	Syracuse. . . .	Latitude .	Polaris .	3		3.45

In the case of the time observations given in the above table, the average azimuths were as follows, namely: at Des Moines, 90°; at Syracuse, 42° 27′; at Syracuse and Malta, 42°.

The observations of the sun give the following results: 57 sets of altitudes, observed to determine latitude, give for the probable error of the mean of a single set $\pm$ 3″.25; and 98 sets of altitudes, observed to determine local time, give for the probable error of the mean of a single set $\pm$ 2″.58. The arithmetical mean of these two values is $\pm$ 2″.92. I therefore adopt as the probable error of the mean of a set of six altitudes of the sun $\pm$ 3″.00 — a result which rests on no less than 930 observed altitudes.

The number of observations on stars, contained in Table I, is not sufficiently great to render it possible to determine a reliable probable error from them, but it is evident that the probable error of an observation of a star is greater than that of an observation of the sun.

To an officer in the field desirous of determining local time, it is a matter of importance to know precisely at what hour angle it will be most advantageous to observe. I have therefore constructed the following table, which will enable a person in any latitude, and with the sun at any declination, to ascertain almost at a glance the altitude, azimuth, and hour angle when the sun is in the most favorable position for time observations. The numerical computations for the table have been made by Mr. Ormond Stone, and in constructing it I have assumed that the altitudes must be confined between sixteen and seventy degrees, these being about the limits of convenient observation with a sextant. δ is the sun's declination.

If we let

$d\zeta$ = probable error of an observed zenith distance, expressed in seconds of arc,
dt = probable error of the corresponding hour angle, expressed in seconds of time,
φ = latitude of the place of observation,
A = azimuth of the sun at the time of observation,

then we shall have

$$dt = \frac{d\zeta}{15 \cos \varphi \, . \, \sin A}$$

by means of which formula I have computed Table III. The azimuths have been taken from Table II, and $d\zeta$ has been assumed equal to $\pm$ 3″.00.

Putting

r = probable error of a single set of observations,
r_0 = probable error of arithmetical mean of m sets of observations,
c = constant error affecting each set of observations,
p_m = weight of the arithmetical mean of m sets of observations,

we have

$$r_0 = \frac{r}{p_m}$$

It is usual to assume p_m proportional to $\sqrt{m}$; but, inasmuch as experience shows that in the case of every instrument there is a limit beyond which increasing the number of observations adds almost nothing to the accuracy of the final result, I have preferred to follow the principles laid down by Dr. B. A. Gould

in his discussion of the weights and mean errors of the observations of Mars and Venus made during the years 1849–'52, and employed to determine the solar parallax.* In accordance with these principles, putting

$$c = ar \qquad\qquad b = \frac{1}{a^2} = \frac{r^2}{c^2}$$

we find

$$p = m \cdot \frac{b + 1}{m + b}$$

b depends solely upon the quality of the observations employed, and increases in the ratio of their accuracy, so that b^2 sets of observations are worth b times as much as one set, but no finite number of sets can ever be worth $b + 1$ times as much as one set. The numerical value of b is arbitrary. For sextant work the observations which I have been able to examine seem to indicate as the most probable value, $b = 3$. That I have adopted, and by substituting it in the formula for p_m, given above, I have computed Table IV.

TABLE IV.—*Weights as Functions of the Number of Observations.*

No.	Weight.	No.	Weight.	No.	Weight.	No.	Weight.	No.	Weight.
1	1.00	6	2.67	12	3.20	25	3.57	50	3.77
2	1.60	7	2.80	14	3.29	30	3.64	60	3.81
3	2.00	8	2.91	16	3.37	35	3.68	75	3.85
4	2.29	9	3.00	18	3.43	40	3.72	100	3.88
5	2.50	10	3.08	20	3.48	45	3.75	1000	3.99

By means of the weights contained in Table IV, I have computed Table V, which, with the argument "Probable error of a single set of observations" gives the probable error of the arithmetical mean of any number of sets of observations not greater than 100. The figures placed at the head of each column indicate the number of sets of observations to the mean of which the probable errors contained in that column apply. The table is used by entering the column headed "1" with the known probable error of a single set of observations; then, on the same line with this known probable error, in the column headed "2" will be found the probable error of the arithmetical mean of two sets of observations; in the column headed "3," the probable error of the arithmetical mean of three sets of observations; and so on for each of the other columns.

* United States Naval Astronomical Expedition to the Southern Hemisphere, Vol. III, page cclii.

TABLE V.—*Probable Error of the Mean of several sets of Sextant Observations, expressed as a Function of the number of sets, there being Six Observed Altitudes in each set.*

In order to meet cases where more or less than six altitudes have been observed in each set, I have made use of the weights contained in Table IV to compute Table VI, which, with the argument "Probable error of the mean of six altitudes" gives the probable error of the mean of various numbers of altitudes, ranging between 1 and 20. The arrangement of this table is similar to that of Table V.

Of course these tables apply only to the probable accidental errors, and afford no clew whatever to the constant errors. In order to get rid of the latter a special investigation must be made for the instrument employed, or else care must be taken to make all the observations in pairs, upon objects at about equal altitudes on each side of the zenith. Table VI shows that almost nothing is gained by observing more than six altitudes in each set, and Table V shows that there is very little use in making more than ten sets of observations for any one object. That is, supposing the constant errors to be entirely eliminated, a latitude depending upon the mean of ten good sets of meridian altitudes is as trustworthy as any that can be found from observations with a sextant; and a chronometer correction depending upon the mean of three sets of altitudes observed to the east, and an equal number observed to the west, of the meridian, the sun being at about the same altitude in each case, is as reliable as any that can be obtained by means of a sextant.

V.—GENERAL REMARKS ON THE OBSERVATIONS FOR TIME AND LATITUDE.

The observations for time and latitude were all made by me, assisted usually by Professor Eastman, who noted the time at a given signal, and then recorded the observation. On two or three occasions I was assisted by Professor Hall, and again by Captain G. L. Tupman. In the first observation that I made at Syracuse I attempted to take up the beat of the chronometer and note the times myself, but I soon abandoned that plan because, owing to noise and other disturbing influences, it did not seem either so accurate or so convenient as to have the times noted by an assistant. The instruments employed were the sextant Stackpole and Brother, No. 937, with a magnifying power of 8.88 diameters on its telescope; the mercurial artificial horizon Ha. 1; and the mean time box chronometer T. S. and J. D. Negus, No. 1115. When observing the sun, half the altitudes were always measured on one limb, with the roof of the artificial horizon in one position, and the other half of the altitudes were measured on the other limb, with the roof of the horizon reversed. When observing stars half the altitudes were measured with the roof in one position, and the other half with it reversed. In the day-time the index correction of the sextant was determined by measuring the diameter of the sun both on and off the arc; at night it was determined by observing the contact of the direct and reflected image of a star.

Throughout this report civil dates are employed. The refractions have been computed by means of Bessel's formula, using the tables given in the Appendix to the Washington Observations for 1845. For latitude observations the tabular part of the reductions to the meridian has been taken from Loomis's Practical Astronomy. All astronomical data required in the reductions have been taken from the American Ephemeris and Nautical Almanac. For further details as to the mode of observing, the formulæ employed in the reductions, &c., reference may be made to my Report on the Total Solar Eclipse of August 7, 1869.*

VI.—OBSERVATIONS FOR TIME.

The observations for time are given in detail in Addendum A to this report, but for convenience of reference the following abstract of them is inserted here. The first column of the table contains the dates; the second column contains the corrections to the chronometer derived from the individual sets of observations made in the forenoon; the third column contains the corrections derived from the sets of observations made in the afternoon; the fourth column contains for each day the mean of the corrections given by the forenoon observations; the fifth column contains for each day the mean of the corrections given by the afternoon observations; the sixth column contains for each day the mean of the numbers given in the fourth and fifth columns, which is taken to be the correction to the chronometer at noon; the seventh column contains the resulting daily rates. The observations on the morning of December 13 were made at the Prima Porta Terra, $0^{s}.13$ east of the Stone Gun-Platform, but in computing the correction to the chronometer at noon of that day the necessary allowance has been made to reduce them to the Stone Gun-Platform.

* $0^s.13$ to the east of Stone Gun-Platform.

At the time of the eclipse, on December 22, I have taken this chronometer to be $1^h\ 2^m\ 45^s.7$ slow of mean time at the Stone Gun-Platform.

The following table contains all the chronometer comparisons made while we were at Syracuse, and I desire to call particular attention to the remarkably good running of the chronometers No. 1115 and No. 1256. Such a result shows the great degree of perfection to which the manufacture of these instruments has been carried.

The chronometer French No. 21778 belonged to Mr. Brothers, ot the English Expedition, and was used by him in timing the exposures of his photographic plates. It had a losing rate of about six seconds per day.

VII.—OBSERVATIONS FOR LATITUDE.

The observations for latitude are given in detail in Addendum B to this report; but for convenience of reference the following abstract of them is inserted here.

Abstract of Results of Observations for Latitude of the Stone Gun-Platform at Syracuse.

Date.	Object.	Latitude.
1870.		° ′ ″
December 13	Sun	+37 3 63
14	Polaris	66
14	Polaris	47
16	Sun	56
16	Sun	58
16	Polaris	37
16	Polaris	43
17	Sun	63
17	Sun	53
18	Sun	62
18	Sun	63
19	Sun	52
19	Sun	57
19	Polaris	54
19	Polaris	67
21	Sun	63
21	Sun	64

Taking separately the mean of the latitudes resulting from observations on the sun, and the mean of the latitudes resulting from observations on Polaris, I find

	°	′	″	″
From the Sun	+ 37	3	59.4	± 0.90
From Polaris			52.3	± 3.38
Mean	+ 37	3	55.9	

As the value from the sun, and that from Polaris, differ from each other by more than the square root of the sum of the squares of their probable errors, I infer that they are affected by a small constant error, and I therefore take their mean as the value of the latitude to be derived from my observations.

Professor Hall's observations at Syracuse, reduced by himself, give for the value of the latitude

	°	′	″
From the Sun	+ 37	3	59.7
From Polaris			35.0
Mean	+ 37	3	47.3

My result for latitude depends on one hundred and two observed altitudes; Professor Hall's on sixty-four observed altitudes. Giving each determination weight in proportion to the number of altitudes on which it depends, I get finally for the latitude of the Stone Gun-Platform

$$+ 37^\circ\ 3'\ 52''.6 \pm 2''.98$$

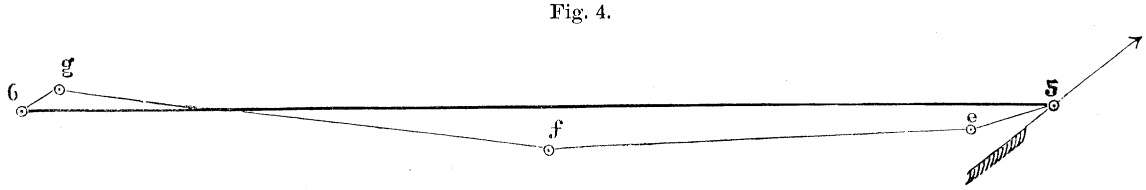
and that value I adopt.

VIII.—TRIANGULATION AT SYRACUSE.

In order to connect our observing station at the Stone Gun-Platform with the various conspicuous land-marks in the city of Syracuse, it was necessary to make a small triangulation.

On passing out of the city toward the main-land, about one-eighth of a mile (200 meters) beyond the fortifications, we come to an open circular space perhaps three hundred feet (98 meters) in diameter. From

Fig. 4.



this circular space four roads radiate. That directed N. 82° W. (true) leads to Avola and Noto. Traveling along it for a little more than half a mile (860 meters) we come to a small stream, crossed by a substantial stone bridge of three arches. Continuing in the same direction about seven-eighths of a mile (1,390 meters) further we come to another fine stone bridge, which, in this case, consists of a single arch spanning the Anapus River. The land between these two bridges is low and marshy, and the road is an artificial causeway protected throughout nearly its whole length by a stone wall on its eastern side. This wall rises about three feet above the surface of the road, and its top is covered with heavy coping-stones. On these coping-stones Professor Hall and I measured the base-line which is shown on a scale of 1 to 10,000 in Figure 4. The causeway was not quite straight, which obliged us to measure the base in four sections; the northern terminus, 5, Fig. 4, being directly above the key-stone in the east face of the central arch of the three-arched bridge; and the southern terminus, 6, Fig. 4, being directly above the key-stone in the east face of the arch over the Anapus River. The measurements were made on December 20, with my Chesterman's metallic tape-line, which is too long in the proportion of 100.134 to 100.000. This explains

the origin of the column, "Corrected distances," in the following table giving the details of the measurement of the base-line:

Stations.	Measured Distances in Feet.	Corrected Distances in Feet.	Corrected Distances in Meters.
From 5 to *e* . .	372.58	372.08	113.41
From *e* to *f* . .	1850.00	1847.52	563.15
From *f* to *g* . .	2150.00	2147.12	654.47
From *g* to 6 . .	187.75	187.50	57.15
	Observed Angles.		
	° ′		
5 *e f*	166 5		
e f g	170 30		
f g 6	144 56		

The following table gives the results of the successive steps in reducing this base to a straight line:

Stations.	Angles.	Distances in Feet.	Distances in Meters.
	° ′ ″		
5 *e f*	166 5 0		
From 5 to *f* . . .		2210.51	673.79
5 *f g*	168 10 47		
From 5 to *g* . . .		4334.28	1321.14
5 *g* 6	150 55 48		
From 5 to 6 . . .		4499.09	1371.38

On December 20 and 21, Professor Hall and I executed, upon this base, the triangulation shown in Fig. 5, which is drawn on a scale of 1 to 15,000. The different stations are designated in the figure by numerals, as follows:

1 is the Stone Gun-Platform, the position of which is described on page 48.

2 is the Light-House on Maniace Castle.

3 is the highest point in the center of the *façade* of the cathedral, which in ancient times was the Temple of Minerva.

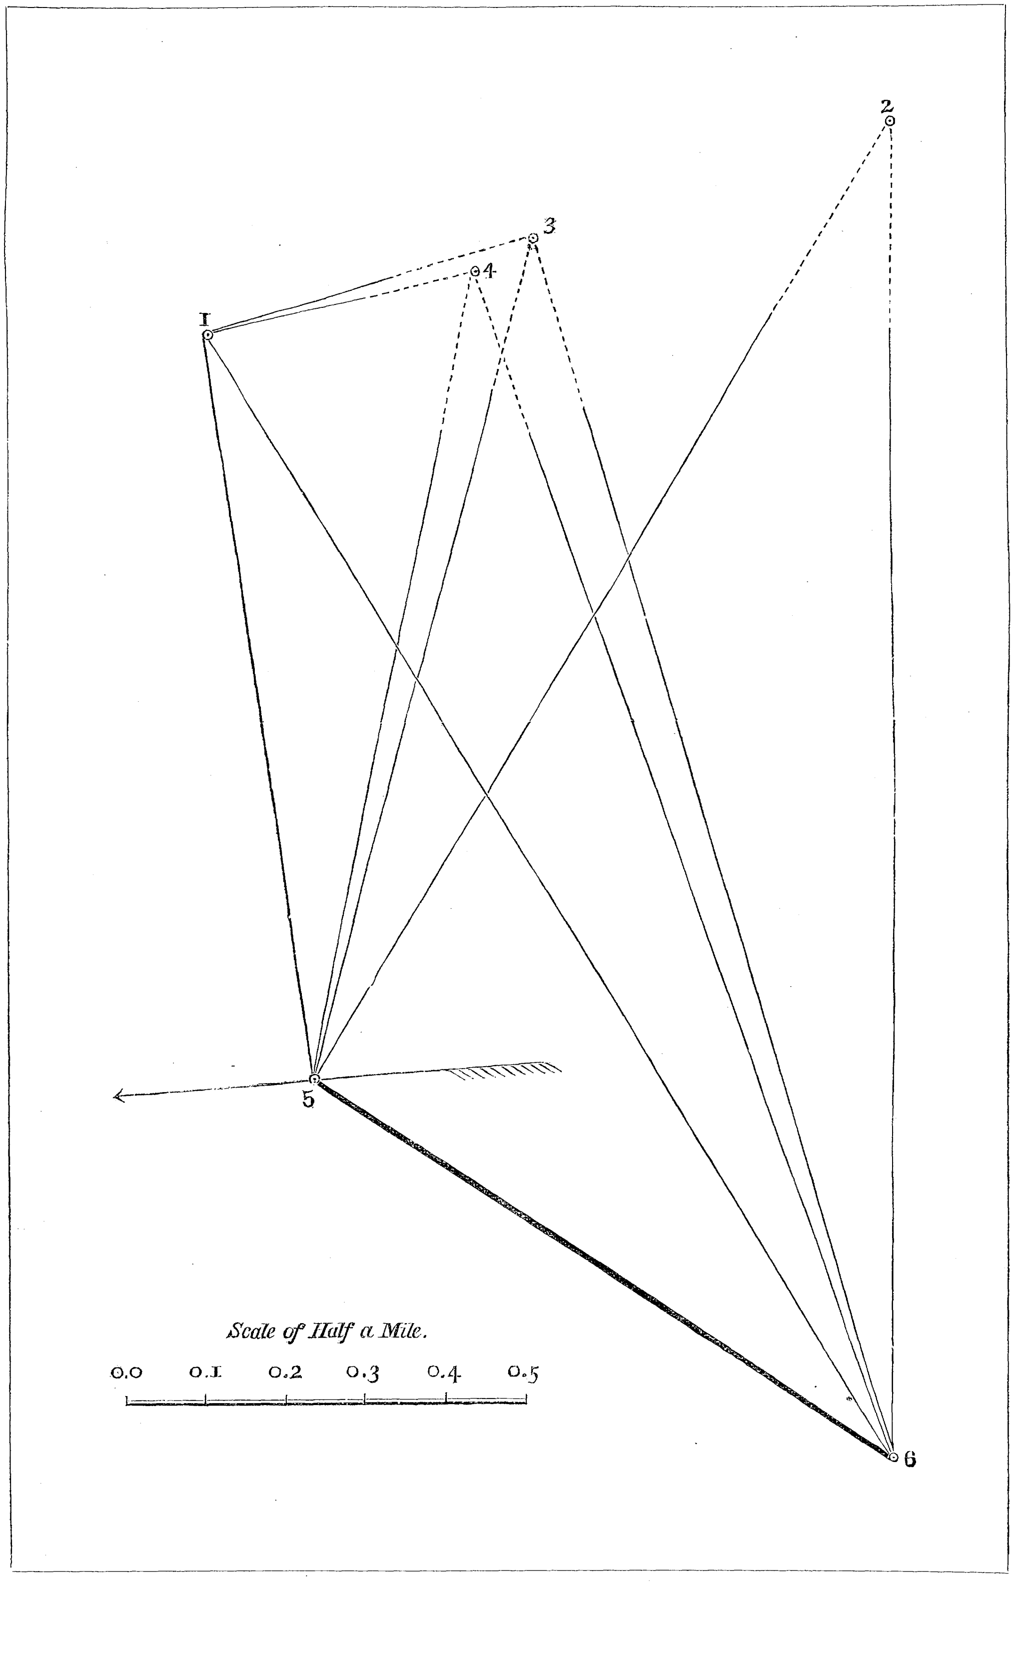
4 is the cupola of the Chiesa del Collegio.

5 is the north end of the base, which is directly above the key-stone in the east face of the central arch of the three-arched bridge.

6 is the south end of the base, which is directly above the key-stone in the east face of the arch of the bridge over the Anapus River.

7 is the Belvedere Tower, which is not shown in the figure.

Fig. 5.



By means of my pocket sextant, Stackpole & Brother, No. 346, the following angles were measured:

Angles at 1.			Angles at 5.			Angles at 6.		
	°	'		°	'		°	'
6 1 5 =	23	9	1 5 2 =	39	11	1 6 2 =	31	14
3 1 5 =	98	24	1 5 3 =	22	45	1 6 3 =	15	2
4 1 5 =	95	13	1 5 4 =	19	25	1 6 4 =	12	0
5 1 7 =	25	24	3 5 2 =	16	16	3 6 2 =	16	12
6 1 7 =	48	32	4 5 2 =	19	40	4 6 2 =	19	12
			4 5 3 =	3	24	4 6 3 =	3	2
			2 5 6 =	92	20	5 6 2 =	56	40
						5 6 1 =	25	27
						5 6 3 =	40	29

By correcting these angles in accordance with the method of least squares, and then converting them into directions, the corrected directions given in the third column of the subjoined table were obtained.

Table of Corrected and Adjusted Directions.

Station.	Object.	Corrected Direction.		Correction by Adjustment.	Adjusted Direction.		
		°	'	'	°	'	"
North Base	Stone Gun-Platform . . .	0	0.0	+0.48	0	0	29
	Cupola of Chiesa del Collegio	19	25.5	− .25	19	25	15
	Cathedral	22	48.5	+ .10	22	48	36
	Light-House	39	7.0		39	7	0
	South Base	131	27.0	− .33	131	26	40
South Base	North Base	0	0.0	+ .38	0	0	22
	Stone Gun-Platform . . .	25	26.9	− .61	25	26	17
	Cupola of Chiesa del Collegio	37	27.4	+ .36	37	27	46
	Cathedral	40	28.9	− .12	40	28	47
	Light-House	56	40.3		56	40	18
Stone Gun-Platform .	Cathedral	0	0.0	− .02	359	59	59
	Cupola of Chiesa del Collegio	3	11.0	+ .04	3	11	2
	South Base	75	15.5	+ .29	75	15	47
	North Base	98	24.0	−0.31	98	23	41
	Belvedere Tower	123	47.8		123	47	48

In order to facilitate the adjustment of this triangulation by the method of least squares, I have adopted the following notation: Retaining the numerical designation of the stations already given, two numbers written one above the other indicate the direction from the station corresponding to the lower number to that corresponding to the upper number; thus, $\frac{1}{5}$ would indicate the direction from 5 to 1, and $\frac{6}{5}$ would indicate the direction from 5 to 6. As the difference of two directions is an angle, $-\frac{1}{5}+\frac{6}{5}$ would indicate the angle 1 5 6. If the numbers are inclosed between brackets they indicate a correction; thus, $[\frac{1}{5}]$ would indicate the correction to the direction $\frac{1}{5}$; $[\frac{6}{5}]$ would indicate the correction to the direction $\frac{6}{5}$, and $[-\frac{1}{5}+\frac{6}{5}]$ would indicate the correction to the angle 1 5 6.

Proceeding in the usual manner,* the quadrilateral 1 4 6 5 furnishes the angle equation

$$180^\circ = 5\,1\,6 + 1\,6\,5 + 6\,5\,1$$

and the side equation

$$\sin 1\,5\,4 \,.\, \sin 5\,6\,4 \,.\, \sin 4\,1\,6 = \sin 4\,1\,5 \,.\, \sin 4\,5\,6 \,.\, \sin 1\,6\,4$$

from which we derive the equations of condition

$$0 = +2.4 - \left[{6 \atop 1}\right] + \left[{5 \atop 1}\right] - \left[{5 \atop 6}\right] + \left[{1 \atop 6}\right] - \left[{1 \atop 5}\right] + \left[{6 \atop 5}\right] \qquad \text{I.}$$

$$\begin{aligned} 0 = +83.3 &- 35.8\left[{1 \atop 5}\right] + 30.7\left[{4 \atop 5}\right] - 16.5\left[{5 \atop 6}\right] - 42.8\left[{4 \atop 6}\right] - 5.2\left[{4 \atop 1}\right] + 4.1\left[{6 \atop 1}\right] \\ &+ 1.1\left[{5 \atop 1}\right] + 5.1\left[{6 \atop 5}\right] + 59.3\left[{1 \atop 6}\right] \end{aligned} \qquad \text{II.}$$

The quadrilateral 1 3 6 5 furnishes the side equation

$$\sin 1\,5\,3 \,.\, \sin 5\,6\,3 \,.\, \sin 3\,1\,6 = \sin 3\,1\,5 \,.\, \sin 3\,5\,6 \,.\, \sin 1\,6\,3$$

from which we derive the equation of condition

$$\begin{aligned} 0 = +43.5 &- 30.0\left[{1 \atop 5}\right] + 25.7\left[{3 \atop 5}\right] - 14.8\left[{5 \atop 6}\right] - 32.2\left[{3 \atop 6}\right] - 5.2\left[{3 \atop 1}\right] + 3.3\left[{6 \atop 1}\right] \\ &+ 1.9\left[{5 \atop 1}\right] + 4.3\left[{6 \atop 5}\right] + 47.0\left[{1 \atop 6}\right] \end{aligned} \qquad \text{III.}$$

These three equations of condition give rise to the following:

Equations of Correlatives.

v	aK_1	bK_2	cK_3
${3 \atop 1}$			− 5.2
${4 \atop 1}$		− 5.2	
${5 \atop 1}$	+ 1	+ 1.1	+ 1.9
${6 \atop 1}$	− 1	+ 4.1	+ 3.3
${1 \atop 5}$	− 1	− 35.8	− 30.0
${3 \atop 5}$			+ 25.7
${4 \atop 5}$		+ 30.7	
${6 \atop 5}$	+ 1	+ 5.1	+ 4.3
${1 \atop 6}$	+ 1	+ 59.3	+ 47.0
${3 \atop 6}$			− 32.2
${4 \atop 6}$		− 42.8	
${5 \atop 6}$	− 1	− 16.5	− 14.8

The resulting normal equations are,

$$\begin{aligned} 0 &= +2.4 + 6.0\,K_1 + 113.7\,K_2 + 94.7\,K_3 \\ 0 &= +83.3 + 113.7 \quad + 7915.8 \quad + 4142.8 \\ 0 &= +43.5 + 94.7 \quad + 4142.8 \quad + 5085.4 \end{aligned}$$

The solution gives

$$\begin{aligned} K_1 &= -\,0.306 \\ K_2 &= -\,0.00808 \\ K_3 &= +\,0.00372 \end{aligned}$$

Substituting these values in the equations of correlatives, we obtain the "Corrections by adjustment" given in the fourth column of the table of corrected and adjusted directions. Applying the corrections by adjustment to the corrected directions, we obtain the adjusted directions given in the fifth column of the same table; and by means of these adjusted directions the whole triangulation has been computed, as follows—the lengths of the sides being given in meters:

For the determination of the azimuths of the sides of the triangles, we have the following angles, measured at the Stone Gun-Platform, late in the afternoon, between the Belvedere Tower and the sun. The instruments employed were my six-inch sextant, Stackpole & Brother No. 937, and the mean time chronometer T. S. & J. D. Negus, No. 1115.

Date.	Time by Negus 1115.			Angle between Sun and Tower.			Limb observed.
1870.	h.	m.	s.	°	′	″	
December 13	2	45	4.5	59	45	20	L.
		45	58.5	59	4	30	R.
		46	35.5	58	57	30	R.
		47	20.0	59	22	10	L.
December 15	2	8	54.0	66	41	0	L.
		10	18.0	65	52	40	R.
		11	33.0		39	30	R.
		12	36.0		58	10	L.
December 16	2	15	35.5	65	31	50	L.
		16	9.0	64	54	20	R.
		16	42.5	64	48	20	R.
		17	12.0	65	13	20	L.

In order to obtain the zenith distance of the Tower, I measured with my pocket-sextant Stackpole & Brother No. 346, the angle included between the Tower and its image reflected from the inclined plane of my black-glass artificial horizon. For the reduction of these observations I have employed the formula

$$\Delta = (90^\circ + a) - \frac{m}{2}$$

in which

Δ=zenith distance of object observed,

m=angular distance between the object and its reflected image,

a=angle included between the inclined reflecting plane and a truly level surface.

In my apparatus there are two inclined black-glass reflectors, designated respectively as A and B. For A, $a=34^\circ\ 58'.8$; and for B, $a=44^\circ\ 59'.1$. When using them care was taken to place them truly at right angles to the vertical plane passing through the eye of the observer and the object to be observed. The following are the observations, together with their reduction:

Date	December 20		December 20	
Inclined plane . .	A		B	
	°	′	°	′
Observed values of m	72	24	92	19
		24		20
		24		21
Mean	72	24.0	92	20.0
Index Correction .		0.0		0.0
Eccentricity . . .	—	0.9	—	0.8
m	72	23.1	92	19.2
$\frac{m}{2}$	36	11.6	46	9.6
$(90^\circ+a)$	124	58.8	134	59.1
Δ	88	47.2	88	49.5

The mean of the two values of $\varDelta$ is 88° 48′.4, which I have adopted.

For the determination of the sun's azimuth we have the formula

$$\tan M = \frac{\tan \delta}{\cos t} \qquad \tan A = \frac{\tan t.\cos M}{\sin(\varphi - M)}$$

where A is to be taken greater or less than 180°, according as t is greater or less than 180°.

A=azimuth of object, counted from the south around by the west.

δ=declination of object.

t=hour angle of object.

φ=latitude of place of observation.

The principal steps in the computation of the azimuth of the Tower will therefore be as follows

	December 13.				December 15.				December 16.			
		h.	m.	s.		h.	m.	s.		h.	m.	s.
Mean of Observed Times		2	46	14.6		2	10	52.5		2	16	24.8

Horizontal ∠, Sun and Tower . . .		59	6	40		65	35	47		64	42	31
Azimuth of Tower		111	35	56		111	36	35		111	37	4

Taking the mean of the three observed values, we have

	°	′	″
Azimuth from Stone Gun-Platform to Belvedere Tower	111	36	32
∠ North Base and Belvedere Tower	25	24	7
Azimuth from Stone Gun-Platform to North Base	86	12	25

The azimuths of such other of the sides as were required, together with the differences of latitude longitude, have been computed by means of the formulæ and tables of the United States Coast Surv The results are appended. The columns headed "Azimuth" and "Distance" contain respectively azimuths and distances from the stations named in the first column to those named in the sixth column. column headed "Back Azimuth" contains the azimuths from the stations named in the sixth colum those named in the first column.

*The formulæ and tables are given in the United States Coast Survey Report for 1860, pp. 361–391. The formulæ are given in my Report on the Total Solar Eclipse of August 7, 1869, Appendix II to the Washington Observations for p. 57.

IX.—TELEGRAPHIC DETERMINATION OF DIFFERENCES OF LONGITUDE.

If we let

$\Delta\lambda =$ difference of longitude between two stations; west longitudes being taken as positive;
$T_e =$ time by face of eastern clock when it sends a signal, and
$T_w =$ time by face of western clock when that signal is received at the western station;
$T'_w =$ time by face of western clock when it sends a signal, and
$T'_e =$ time by face of eastern clock when that signal is received at the eastern station;
$t =$ time occupied in the passage of a signal from one station to the other;
$\Delta T_e, \Delta T'_e, \Delta T_w$, and $\Delta T'_w =$ respectively the corrections necessary to reduce the time indicated by the faces of the eastern and western clocks to true local time at the instants T_e, T'_e, T_w, T'_w;

then, neglecting personal equation, when the eastern clock sends and the signals are received at the western station, we shall have

$$\Delta\lambda - t = (T_e - T_w) + (\Delta T_e - \Delta T_w)$$

and when the western clock sends, and the signals are received at the eastern station, we shall have

$$\Delta\lambda + t = (T'_e - T'_w) + (\Delta T'_e - \Delta T'_w)$$

from which we get

$$\Delta\lambda = \frac{(T_e - T_w) + (T'_e - T'_w)}{2} + \frac{(\Delta T_e - \Delta T_w) + (\Delta T'_e - \Delta T'_w)}{2}$$

$$t = \frac{(T'_e - T'_w) - (T_e - T_w)}{2} + \frac{(\Delta T'_e - \Delta T'_w) - (\Delta T_e - \Delta T_w)}{2}.$$

If the rates of the clocks are small, the second term in the expression for the value of t may usually be neglected.

Difference of Longitude between Syracuse and Malta.

The observations at Syracuse were made by me, at the Stone Gun-Platform, and have already been given in detail on page 59. The observations at Malta were made by Professor Hall, with the Pistor and Martins patent sextant No. 107, of six inches radius, a mercurial artificial horizon, and the mean time chronometer T. S. & J. D. Negus No. 1228. On December 13, he observed at Spencer's Monument; on December 14, 15, and 16, he observed on the flat roof of the Telegraph Office, which, according to the Ordnance survey map on a scale of 1 to 2500, is 6040 feet north, and 760 feet east, of Spencer's Monument. The reduction from the Telegraph Office to Spencer's Monument will therefore be, in latitude $-59''.73$, and in longitude $+ 9''.23 = + 0^s.615$.

Professor Hall obtains from his observations the following results:*

Observations for Latitude.

Date.	Station.	Object.	No. of Altitudes.	Observed Latitude of Station.	Resulting Latitude of Spencer's Monument.
1870.				° ′ ″	° ′ ″
Dec. 13	Spencer's Monument . .	Sun . .	16	+ 35 52 55	+ 35 52 55.
14	Telegraph Office . . .	Sun . .	12	54 0	60.3
15	Telegraph Office . . .	Sun . .	8	54 23	83.3

The mean of the three results is $35° 53' 6'' \pm 5''.8$; but as a comparison of the adopted latitude of Syracuse with that obtained from Professor Hall's sextant observations shows the latter to be $7''$ too large, I subtract that amount from the mean given above, and obtain finally

Latitude of Spencer's Monument $= + 35° 52' 59'' \pm 5''.8$

*For the observations in detail see pages 30 to 38.

Chronometer T. S. & J. D. Negus No. 1228 *slow of Local Mean Time, by Observation.*

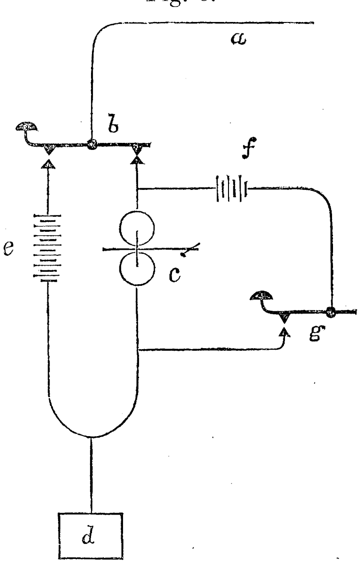
22	Stone Gun-Platform, Syracuse	37.2		

* Reduction to Telegraph Office = + $0^s.6$.

The telegraph line between Malta and Syracuse is made up of 56½ knots = 65.1 statute miles = 104.8 kilometers of submarine cable, and 155.4 statute miles = 250 kilometers of wire stretched in the air. The total length of the line is therefore 220½ miles = 354¾ kilometers. The battery at Malta consisted of twenty small-sized Daniels cells, (Pile Callaud, Italian model,) while that at Syracuse consisted of twenty small-sized Daniels cells with the liquids in contact, known in Italy as the "Pila Callaud a strozzatura senza diaframma." The arrangement of the instruments on the line was such as is never seen in the United States, but I believe it is quite common in Europe. At each station there was a galvanic battery, *e*, Fig. 6; a polarized receiving-magnet, *c*, which recorded the signals with ink upon a long fillet of paper running at the rate of about eight-tenths of an inch per second; a transmitting-key, *b*, having a front and a back contact; and an earth-plate, *d*. The battery *e* had one of its poles connected with the earth-plate *d*, and the other attached to a point under the front contact of the key *b*. The polarized receiving-magnet *c* had one end of its coil connected with the earth-plate *d*, and the other end attached to a point under the back contact of the key *b*. The line wire *a*, coming in from the distant station, was attached to the axis of the key *b*, which, when not in use for sending signals, habitually rested on its back contact, and thus put the line to earth through the receiving-magnet *c*. Things being in this condition, any current arriving from the distant station was at once made evident by the receiving-magnet *c*. If it was desired to send a signal to the distant station, the key *b* was depressed, thus breaking the contact between the earth and the line, and establishing a connection between the latter and the battery *e*. In order to render this apparatus as convenient as possible for the exchange of longitude signals, I added to it the local battery *f* and the key *g*, connected with the receiving-magnet *c*, in the manner shown in the figure.

Fig. 6.



The following was the

PROGRAMME FOR THE DETERMINATION OF DIFFERENCE OF LONGITUDE.

1. Mean time box chronometers, beating half-seconds, will be used at each station, and their corrections and rates will be determined by means of observations on the sun, made both in the morning and in the afternoon, with sextants and mercurial artificial horizons. In order to eliminate constant errors, care will be taken that the observations in the morning and in the afternoon are made with the sun at about the same altitude; that in each case an equal number of altitudes are taken on one limb of the sun with the roof of the horizon in one position, and on the other limb of the sun with the roof of the horizon reversed; and that the index error of the sextant employed is well determined with each set of observations.

2. The time of exchanging signals will necessarily depend upon the convenience of the Telegraph Company, but about 1 p. m. will be the most desirable hour. At the conclusion of the telegraphic work of each day, the time of exchanging signals on the day following will be agreed upon.

3. Signals will be exchanged in the following manner: The officer at Syracuse will ask the officer at Malta if everything is ready, and, upon receiving an affirmative reply, he will wait until his chronometer indicates 50 seconds, and then he will make a rattle with the key *b*, Fig. 6, of his apparatus. This rattle will consist of ten or fifteen dots made at the rate of about five per second. Next he will make a series of taps on the key *b*, in exact coincidence with the beats of his chronometer at 0, 1, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 0, 1, 5, &c., seconds, and this he will continue for three minutes, ending at 0 seconds. Then he will pause for five seconds, and finally finish with a rattle; after which he will record the hour and minute of the last tap before the rattle. As soon as the officer at Malta hears the first rattle of the officer at Syracuse, he will start his recording apparatus, if it is not already running, and will commence making taps on the key *g* of his instrument, in exact coincidence with the beats of his chronometer, and at intervals of one second; taking care to mark the beginning of each minute by omitting the tap corresponding to 0 seconds of the chronometer. This will be continued until the arrival of the second rattle from Syracuse, when he will cease tapping, and will record the hour and minute corresponding to the last tap which was omitted before the arrival of the rattle. He will then notify the officer at Syracuse whether or not his signals have been properly received. If they have not been, they will be repeated; if they have been, the officer at Syracuse will telegraph to the officer at Malta the hour and minute corresponding to his last tap.

The taps on the Malta key *g* will mark upon the Malta fillet a series of dots corresponding to the seconds of the Malta chronometer, thus producing a time scale in which the beginning of each minute will be designated by the omission of the dot corresponding to 0 seconds. Upon this time scale the taps on the Syracuse key *b* will record a series of dots corresponding to each fifth second of the Syracuse chronometer, and the beginning of each minute of that chronometer will be designated by two dots at an interval of one second. The hour and minute of each chronometer corresponding to the beginning of one of its minutes upon this time scale being known, it is evident that a very accurate comparison of the two chronometers will be obtained by simply reading off the scale.*

As soon as the officer at Malta has been notified of the hour and minute corresponding to the last signal sent from Syracuse, he will ask the officer at Syracuse if he is ready to receive signals from Malta, and upon receiving an affirmative reply the operations described above will be repeated, except that this time the signals will be sent by the officer at Malta tapping upon his key *b*, and will be received upon the Syracuse register *c*, while the officer there is tapping seconds upon his key *g*.

The following are the numerical details of the work. Each line in the columns headed "Number of Signals" gives the number of signals read off from the fillet, the mean of which furnished the chronometer comparison recorded on the same line. The headings of the other columns will be sufficiently intelligible without explanation, if it is borne in mind that the notation employed is that given on page 70.

Comparison of Chronometers obtained by reading off the Syracuse Fillet.

Date.	No. of Signals.	Negus 1115 at Syracuse.		Negus 1228 at Malta.	$(T'_e - T'_w)$

* From a discussion of 164 signals, exchanged between Syracuse and Malta, Professor Hall finds that the probable error of a chronometer comparison made by means of a single signal is only ± 0.034 of a second.

The probable error of a chronometer comparison obtained from the mean of thirty signals is about $\pm 0^s.007$.

As the rates of the chronometers were small, I assume $\Delta T_e = \Delta T'_e$, and $\Delta T_w = \Delta T'_w$. By means of a simple interpolation the tables on pages 59 and 71 furnish the

Chronometer Corrections at the Time of the Exchange of Signals.

Date.	Negus 1115 at Syracuse.	Negus 1228 at Malta.	$(\Delta T_e - \Delta T_w)$
1870.	h. m. s.	h. m. s.	h. m. s.
Dec. 13.	+ 1 2 43.20	+ 0 57 29.55	+ 0 5 13.65
14	43.95	28.52	15.43
15	44.41	28.70	15.71
16	44.70	29.25	15.45

Resulting Differences of Longitude and Wave Times.

Date.	$\frac{1}{2}(T'_e - T'_w)$	$\frac{1}{2}(T_e - T_w)$	$(\Delta T_e - \Delta T_w)$	$\Delta\lambda$	t
1870.	h. m. s.	h. m. s.	h. m. s.	h. m. s.	s.
Dec. 13	− 0 1 2.11	− 0 1 2.12	+ 0 5 13.65	+ 0 3 9.42	+ 0.01
14	2.24	2.22	15.43	10.97	− .02
15	2.41	2.38	15.71	10.92	− .03
16	2.60	2.62	15.45	10.23	+ .02

The negative values of t probably indicate that that quantity is less than the personal equation of the observers in tapping. If we give half weight to the result of December 13, we get

$$\Delta\lambda = + 0^h\ 3^m\ 10^s.52 \pm 0^s.21$$

But an application of Peirce's criterion shows that the result of December 13 should be rejected; and as the time observations at Malta on that day were made on one side of the meridian only, and in consequence may be affected by a considerable constant error, I have discarded it. The mean of the remaining three results is

$$\Delta\lambda = + 0^h\ 3^m\ 10^s.71 \pm 0^s.16$$

which I adopt as the best value obtainable from our work.*

It would seem that time determined by means of sextants used in the manner described above must be free from all personality; but, in order to make sure of this point, I compared Professor Hall's chronometer corrections, given on page 71, with my own, given on page 59, by means of the chronometer comparisons given on page 60. In that way I found that the correction necessary to reduce Professor Hall's time to mine was, on December 17, $+ 0^s.1$; on December 18, $+ 0^s.1$; on December 19, $+ 0^s.8$; and on December 21, $+ 0^s.5$. These numbers might be taken as an indication of a personal equation; but, as they are less than the change in the difference between the results of the forenoon and afternoon observations on these very days, I prefer to consider them as accidental errors, and to assume that no real personal equation exists.

*If we assume Professor Hall's chronometer to have had a constant rate from December 14 to December 21, then each of the three corrections observed at Malta will furnish an equation of condition involving the correction at a given date, the rate, and the difference of longitude between Syracuse and Malta; and each of the four corrections observed at Syracuse will furnish an equation of condition involving the correction at the given date, and the rate. Solving these equations by the method of least squares, the chronometric difference of longitude will be found to be $0^h\ 3^m\ 10^s.23$.

Our final result for difference of longitude will therefore be

	h.	m.	s.
Stone Gun-Platform, Syracuse, east of Telegraph Office, Malta	0	3	10.71
Spencer's Monument, west of Telegraph Office at Malta		+	0.615
Light on Maniace Castle, east of Stone Gun-Platform, Syracuse		+	0.861
Light on Maniace Castle, Syracuse, east of Spencer's Monument, Malta .	0	3	12.19 ± 0^s.16

The English Admiralty chart, dated December 10, 1869, gives, as the difference of longitude between these two points, $0° 47' 24'' = 0^h 3^m 9^s.6$, a value which is too small by $2^s.6 = 39''$.

Difference of Longitude between Malta and Gibraltar.

The observations at Malta were made by Professor Hall, as described above. Those at Gibraltar were made by Professor Newcomb, with a Gambey sextant of seven inches radius and a mercurial artificial horizon; and as he observed in three different localities, it is desirable, in the first place, to determine the reduction from each of these localities to some well-marked position. In order to accomplish this with as much accuracy as possible, I procured a copy of the English Admiralty chart of Gibraltar, dated July 27, 1869, the topography upon which is from the Ordnance plan of 1868, and the scale of which is 1.00 inch to 1031 feet. Upon this chart the Signal Tower and the Base of the New Mole were marked, and Professor Newcomb was kind enough to point out on it the exact location of the Telegraph Office and the approximate positions of the American Consul's House and of his station at Buena Vista. Then, by means of the ordinates given on page 9 of his report, I laid off the position of Buena Vista Station from the Signal Tower, from the Base of the New Mole, and from the Telegraph Office. To my surprise I obtained three different points, two of which fell in the sea. To unravel the difficulty, I laid down on a piece of tracing-paper the relative positions of the Telegraph Office, the American Consul's House, the Signal Tower, the Base of the New Mole, and Buena Vista Station, employing for that purpose the scale of the chart and Professor Newcomb's co-ordinates. Then superposing the tracing-paper on the chart in such a manner that the Signal Tower and the Base of the New Mole marked upon the former fell over the same points marked upon the latter, I found that all the other points marked on the paper also coincided with the corresponding points on the chart as accurately as could be expected when it was considered that the measurements of the ordinates were only made to the nearest hundred feet. Distributing the outstanding differences as evenly as possible among the several known stations, I transferred the positions of Buena Vista Station and the American Consul's House to the chart with all desirable accuracy by pricking them through from the tracing-paper. From the position of Buena Vista Station thus determined the ordinates of the other stations were measured on the chart, and the results are given in the columns X and Y of the following table; the axis of X being taken in the meridian, and that of Y in the prime vertical. The numbers in the columns r and A have been computed from those in the columns X and Y by means of the formulæ

$$r = 1031\sqrt{X^2 + Y^2} \qquad \tan A = \frac{Y}{X}$$

r being the distance and A the azimuth from Buena Vista to any other station. The numbers in the columns r' and A' have been computed from Professor Newcomb's co-ordinates by means of the formulæ

$$r' = \sqrt{X'^2 + Y'^2} \qquad \tan A' = \frac{Y'}{X'}$$

Station.	Admiralty Chart.				Newcomb.		$A' - A$
	X	Y	r	A	r'	A'	
	in.	in.	feet.	° ′	feet.	° ′	° ′
Telegraph Office	8.42 N.	2.12 W.	8950	165 51	8910	170 58	+ 5 7
American Consul's House .	6.63 N.	1.32 W.	6970	168 45	6950	173 23	+ 4 38
Signal Tower	5.60 N.	0.58 E.	5800	185 56	5710	191 9	+ 5 13
Flag-Staff at Landing-Place .	2.60 N.	1.80 W.	3260	145 19			
Base of New Mole	2.50 N.	2.08 W.	3350	140 14	3360	143 27	+ 3 13

A comparison of the distances in the columns r and r' shows that they are as nearly identical as could be expected, considering the rough nature of Professor Newcomb's measurements; but the azimuths in the columns A and A' differ from each other considerably, as shown in the column $A'–A$, and indicate an angle of about five degrees between the direction of the meridian employed by Professor Newcomb and that of the Admiralty chart. Adopting the meridian of the chart, I find the following reductions necessary in passing from the stations named to Buena Vista:

Station.	Reduction in Latitude.	Reduction in Longitude.
	′ ″	′ ″
Telegraph Office	— 1 25.8	— 0 26.7
American Consul's House .	— 1 7.6	— 0 16.6
Flag-Staff at Landing-Place .	— 0 26.5	— 0 22.6

The minus sign before a reduction in latitude, or longitude, indicates that the station to which it belongs is further north, or further west, than Buena Vista.

Professor Newcomb obtains from his observations the following results:*

Observations for Latitude.

Date.	Station.	Object.	No. of Altitudes.	Observed Latitude of Station.	Resulting Latitude of Buena Vista.
1870.				° ′ ″	° ′ ″
Dec. 15	Telegraph Office . . .	Sun . .	6	+ 36 8 25	+ 36 6 59.2
15	Telegraph Office . . .	Polaris .	5	8 25	59.2
20	Buena Vista Station . .	Sun . .	6	6 44	44.
26	American Consul's House	α Ceti . .	5	7 41	33.4
26	American Consul's House	Polaris .	6	8 12	64.4

Taking the means, I find

	°	′	″
From the Sun and α Ceti	+ 36	6	45.5
From Polaris			61.8

which seems to indicate that the observations are affected by a constant error amounting to 8″.1. Correcting for this error, I obtain finally

$$\text{Latitude of Buena Vista Station} = +36^\circ\ 6'\ 53''.6 \pm 2''.8$$

* For the observations in detail see pages 17 to 21.

Chronometer T. S. & J. D. Negus, No. 1265, fast of Local Mean Time by Observation.

The reduction of a chronometer correction from the Telegraph Office to Buena Vista is $+1^s.78$.

The length of the submarine telegraph cable between Malta and Gibraltar is 1025 knots = 1389 statute miles = 2235 kilometers. It is worked by means of condensers, no battery current being allowed to enter the line. The instruments employed for the purposes of communication are Sir William Thomson's reflecting galvanometers. For information as to the method of sending and receiving the longitude signals reference may be made to page 24 of Professor Newcomb's report and page 41 of Professor Hall's report. The following are the numerical details of the work:

Comparison of Chronometers obtained from the Signals received at Malta.

Date.	Number of Signals.	Negus 1228 at Malta.		Negus 1265 at Gibraltar.	$(T_e - T_w)$
1870.		h. m. s.		h. m. s.	h. m. s.
Dec. 15	18	4 47 43.68	=	4 48 0.00	−0 0 16.32
16	21	23 34 43.05	=	23 35 0.00	16.95

Comparison of Chronometers obtained from the Signals received at Gibraltar.

Date.	Number of Signals.	Negus 1228 at Malta.		Negus 1265 at Gibraltar.	$(T'_e - T'_w)$
1870.		h. m. s.		h. m. s.	h. m. s.
Dec. 15	18	4 55 0.00	=	4 55 17.34	−0 0 17.34
16	17	23 42 0.00	=	23 42 18.13	18.13

The probable error of a chronometer comparison obtained from the mean of eighteen signals is about $\pm 0^s.01$.

As the rates of the chronometers were small, I assume $\varDelta T_e = \varDelta T'_e$, and $\varDelta T_w = \varDelta T'_w$. The corrections of the chronometers at the times of exchanging signals have been obtained as follows: A simple interpolation among the numbers contained in the table on page 71 gives, for the correction to the Malta chronometer on December 15, $+ 0^h\ 57^m\ 28^s.72$. By means of the known difference of longitude, and the telegraphic comparison of chronometers, the Syracuse observations give, for the correction of the Malta chronometer on the same date, $+ 0^h\ 57^m\ 28^s.91$. The mean of these two results is $+ 0^h\ 57^m\ 28^s.82$, which I adopt. In the same way, on December 16 I find the correction of the Malta chronometer to be, from the Malta observations, $+ 0^h\ 57^m\ 29^s.22$, and from the Syracuse observations, $+ 0^h\ 57^m\ 28^s.78$. The mean is $+ 0^h\ 57^m\ 29^s.00$, which I adopt. The mean of Professor Newcomb's observations at Gibraltar, on December 15, gives, for the correction of his chronometer at $6^h\ 50^m$ p. m. on that day, $- 0^h\ 22^m\ 16^s.52$. A comparison of this correction with that obtained on December 20 gives, for the rate of the chronometer, $-1^s.21$ per day, allowance having been made for the difference of longitude between the Telegraph Office and Buena Vista. The correction of this chronometer, when it indicated $4^h\ 51^m$ p. m. on December 15, was therefore $- 0^h\ 22^m\ 16^s.42$. On December 16, at $7^h\ 45^m$ p. m., the observations make the correction $- 0^h\ 22^m\ 14^s.6$, and, by interpolating between this result and that of the day before, the correction at $11^h\ 38^m$ a. m. becomes $- 0^h\ 22^m\ 15^s.2$. If, on the other hand, we carry forward the correction from December 15 by means of the rate given above, we get $- 0^h\ 22^m\ 17^s.37$. Collecting our results, we have the following table of

Chronometer Corrections at the Time of the Exchange of Signals.

Date.	Negus 1228 at Malta.	Negus 1265 at Gibraltar.	$(\Delta T_e - \Delta T_w)$
1870.	h. m. s.	h. m. s.	h. m. s.
Dec. 15	+ 0 57 28.82	− 0 22 16.42	+ 1 19 45.24
16	29.00	15.2	44.2
16	29.00	17.4	46.4

Resulting Differences of Longitude and Wave Times.

Date.	$\frac{1}{2}(T_e - T_w)$	$\frac{1}{2}(T'_e - T'_w)$	$(\Delta T_e - \Delta T_w)$	$\Delta\lambda$	t
1870.	h. m. s.	h. m. s.	h. m. s.	h. m. s.	s.
Dec. 15	− 0 0 8.16	− 0 0 8.67	+ 1 19 45.24	+ 1 19 28.41	+ 0.51
16	8.48	9.06	44.2	26.7	.58
16	8.48	9.06	46.4	28.9	

On December 13, 14, 15, and 16, Negus 1115 was compared with two other chronometers at Syracuse, and, by means of the telegraph, with the Malta chronometer also. These comparisons show, beyond all question, that the latter instrument was running regularly, and, from an interval of seven days, Professor Hall's observations give it a daily gaining rate of $0^s.09$, but my own observations make the rate zero. The telegraphic comparisons of this instrument with the Gibraltar chronometer, on December 15 and 16, show that the latter was certainly gaining not less than $1^s.00$ per day, while Professor Newcomb's time determinations on these days give it a losing rate of $1^s.89$. It therefore follows that at least one of the time determinations must be affected by a large error. That on December 15 depends upon observations of four different objects, three of them being to the west, and one to the east, of the meridian, and all giving nearly the same chronometer correction; while that on December 16 depends upon a single set of five altitudes of α Lyræ. Under the circumstances there cannot be the least hesitation in rejecting the latter, and with it the resulting value of $\varDelta\lambda$, which is $+1^h\ 19^m\ 26^s.7$. From the method employed in arriving at the other value of the Gibraltar chronometer correction on the same day, it is evident that the resulting $\varDelta\lambda$ depends almost wholly on the time determination of the 15th, and I therefore reject it also, and adopt the first value given in the table above, namely, $\varDelta\lambda = +1^h\ 19^m\ 28^s.41$.

The observations for time having been made with sextants, used in such a manner as to eliminate all

constant errors, I assume that they are free from personal equation. The probable errors of the chronometer corrections, on December 15, are as follows: At Malta $\pm$ 0^s.07, derived from the discrepancies between the adopted correction and the corrections given, respectively, by Professor Hall's observations and my own. At Gibraltar $\pm$ 0^s.13, derived from the discrepancies between the individual corrections and the mean of the whole. The probable error of the telegraphic comparison of chronometers is $\pm$ 0^s.01. Hence the probable error of $\Delta\lambda$ is $\pm$ 0^s.15.

Our final result for difference of longitude will therefore be:

	h	m	s
Telegraph Office, Malta, east of Telegraph Office, Gibraltar	1	19	28.41
Spencer's Monument, west of Telegraph Office, Malta		—	0.615
Flag-Staff at Landing-Place, east of Telegraph Office, Gibraltar . .		—	0.271
Spencer's Monument, Malta, east of Flag-Staff, Gibraltar	1	19	27.52 $\pm$ 0^s.15

X.—GEOGRAPHICAL POSITIONS DETERMINED BY THE UNITED STATES NAVAL OBSERVATORY PARTIES.

Collecting our results, and rejecting superfluous figures, we have the following

Table of Geographical Positions.

[North Latitudes and West Longitudes are taken as positive.]

Station.	Latitude.	Longitude in Arc from Greenwich.	Longitude in Time from Greenwich.	Longitude in Time from Washington.
	° ′ ″	° ′ ″	h. m. s.	h. m. s.
Flag-Staff at Landing-Place, Gibraltar .	+ 36 7 20	+ 5 20 45	+ 0 21 23.0	− 4 46 49.0
Buena Vista Station, Gibraltar	36 6 54	+ 5 20 22	+ 0 21 21.5	4 46 50.5
Spencer's Monument, Malta	35 52 59	− 14 31 8	− 0 58 4.5	6 6 16.5
Stone Gun-Platform, Syracuse	37 3 53	15 18 57	1 1 15.8	6 9 27.8
Prof. Harkness' Telescope, Syracuse. .	37 3 52	15 18 57	1 1 15.8	6 9 27.8
Prof. Eastman's Telescope, Syracuse. .	37 3 52	15 18 58	1 1 15.9	6 9 27.9
Mr. Brothers' Telescope, Syracuse . .	37 3 50	15 18 58	1 1 15.9	6 9 27.9
Light-House on Maniace Castle, Syracuse	+ 37 3 8	− 15 19 10	− 1 1 16.7	− 6 9 28.7

Owing to a break in the telegraph cable between Gibraltar and Lisbon, Professor Newcomb was unable to connect his station with Greenwich, and I have therefore made all our longitudes depend upon the position of the Flag-Staff, at the Landing-Place, in Gibraltar, which I have taken to be 0^h 21^m 23^s.0 west of Greenwich.

In order to show precisely how much the positions given by our observations differ from those heretofore adopted, I append the following list, which is made up from the latest English Admiralty charts. The columns dL and dM contain respectively the corrections which must be applied to the latitudes and longitudes of the charts in order to reduce them to our own.

Station.	Latitude.	dL	Longitude.	dM	Date of Chart.
	° ′ ″	″	° ′ ″	″	
Flag-Staff at Landing-Place, Gibraltar . .	+ 36 7 10	+ 10	+ 5 20 45	0	July 27, 1869
Spencer's Monument, Malta	35 53 0	− 1	− 14 31 0	− 8	Aug. 16, 1861
Light-House on Maniace Castle, Syracuse .	+ 37 3 0	+ 8	− 15 18 24	− 46	Dec. 10, 1869

XI.—MAGNETIC DECLINATION AT SYRACUSE.

In order to determine the magnetic declination, I made the following observations of the bearing of the Belvedere Tower, from the Stone Gun-Platform, with my prismatic compass, the card of which is divided to single degrees, and numbered from 0° to 360°; 0° corresponding to the magnetic south, and the numbers increasing toward the west. It has an index error of + 0°.6. The true bearing of the Belvedere Tower was N. 68° 23′ W. = 111°.6.

Date.	Time.	Magnetic Bearing of the Belvedere Tower.	Resulting Magnetic Declination.
1870.		°	°
Dec. 16	4.00 p. m.	124.0	12.4 west
17	12.30 p. m.	124.0	12.4 west
18	9.40 a. m.	124.0	12.4 west
21	8.10 a. m.	123.9	12.3 west

Taking the mean, we have

Observed magnetic declination	12° 22′ west.
Correction for index error of compass	— 36′
True magnetic declination	11° 46′ west.

The probable error of this result I estimate at ± 8′.

XII.—OBSERVATIONS ON THE DAY OF THE ECLIPSE.

Before describing the observations on the day of the eclipse, I must not forget to mention that, without even a hint from us that such a thing would be desirable, the Prefect most kindly directed the military commandant, Lieutenant Colonel Augusto Rossi, to furnish a sufficient number of troops to insure the maintenance of order and quiet in the neighborhood of our observing station on that occasion. For this purpose the bastion was guarded by a battalion of infantry from a little before noon till after the eclipse was over, and, although a great crowd of people gathered in the street opposite, we were enabled to make our observations without any interruption. We owe the Prefect and Lieutenant Colonel Rossi sincere thanks for their thoughtfulness in contributing to our success.

While at Malta I was so fortunate as to make the acquaintance of Captain G. L. Tupman, of the Royal Marine Artillery, who was at that time attached to the English iron-clad ship of war Prince Consort. Being an enthusiastic amateur astronomer, he became interested in our expedition and most generously volunteered to assist me in the spectroscopic observations, by directing the finder of my telescope to the various parts of the corona which it might be desirable to examine. He arrived in Syracuse on the morning of Wednesday, December 21, and rendered most efficient service, not only during the eclipse itself, but also in much of the preliminary and subsequent work. His letter describing his observations forms Addendum D to this report, and it affords me great pleasure to place on record an acknowledgment of the obligations which the expedition owes to him.

For eight days after our arrival in Sicily the weather was superb; but on December 20 a change took place, the barometer began to fall, the wind began to rise, and, although at times the heavens were perfectly clear, still for the most part they were either completely overcast or else flecked with drifting clouds, and this state of affairs continued long after we left Syracuse. However, at the beginning of the eclipse the sky in the neighborhood of the sun was perfectly clear, and I observed the first contact with my three-inch telescope, armed with a Huygenian eye-piece magnifying 65½ diameters, at $11^h\ 35^m\ 27^s.5$ by the face of the chronometer Negus 1115. As the eclipse advanced I looked very carefully for the bright line which was shown in such a marked manner along the edge of the moon's limb in the photographs taken by Dr. Curtis, at Des Moines, in August, 1869, but, although I used both red and neutral tint shade glasses, and the definition in the telescope was excellent, I could not see any trace of it till $12^h\ 8^m$, when I fancied I saw a very faint and narrow bright line, but I am far from being certain that such a line really existed. In fact, I am inclined to think it was only the effect of contrast between the bright sun and the dark moon.

With the assistance of Captain Tupman, about $12^h\ 20^m$ I attached the spectroscope to the telescope, applied the necessary counterpoises, placed the slit so that it was inclined from a vertical circle about ten or fifteen degrees toward the north, and adjusted the needle in the finder so that when its point fell upon a horn of the solar crescent the image of that horn fell accurately within the jaws of the slit. A quarter of an hour before totality a dense cloud came over the sun and hid it entirely. The wind was blowing half a gale, and although my telescope, with its solid substantial mounting, was under the lee of the parapet of the bastion, it was far from being so steady as was desirable. When I tried to light my lanterns I found it was impossible, even in the most sheltered place, and I was obliged to take them into the store-house and light them there. In carrying them back to the telescope one was blown out, but by crouching down behind the parapet and sheltering it with our bodies, Captain Tupman and I succeeded in lighting it again, after which I attached it to the spectroscope to illuminate the micrometer scale. It was now within less than five minutes of totality, and fortunately the cloud covering the sun was fast becoming thinner. Presently a slender crescent, which was all that remained of the solar disk, became visible, dwindled rapidly away, and at $1^h\ 0^m\ 11.^s0$ I observed the commencement of totality with my naked eye. The cloud was sufficiently transparent to allow the corona to be seen through it, but, of course, much diminished both in extent and brilliancy, and I do not think it was more than half or two-thirds as extensive as that which I witnessed at Des Moines in August, 1869. On that occasion it had a well-marked trapezoidal form, but this time it seemed to me to be nearly circular; however, my view of it was limited to a mere glance at the commencement of totality, and it may have appeared differently afterward. The general illumination of the atmosphere was considerable; in fact, it was not really dark, for, in addition to the outlines of objects, the details were also visible to a considerable extent.

I spent the first ten or fifteen seconds of the totality in examining the corona with an Arago polariscope. This instrument consists of a plate of selenite and a double-image prism, placed almost in contact with each other, and mounted in a brass cell, 0.43 of an inch thick, for the purpose of slipping on to an eye-piece, so that it may be used for telescopic observation. The eye-piece contains a diaphragm of such diameter that when it is seen through the polariscope two circular fields of view appear, tangent to each other; and if polarized light is present these fields of view are of complementary colors. When the cell is removed from the eye-piece its field of view has no longer any well-defined boundary, and if a beam of polarized light is then examined with it the effect of the prism will be to displace one portion of the beam upon another, and no complementary colors can appear except at the very edge of the field. Now, bearing in mind that the separating angle of the prism is $2°\ 31'$, let us apply this to the case of the eclipse. Looking at the corona through the polariscope, two images of it will be seen well separated from each other, and everywhere else one portion of the sky will be displaced upon another portion $2°\ 31'$ distant. Under these circumstances, no matter whether the sky is polarized or not, it can exhibit only its natural color, unless, indeed, the polarization varies so rapidly that its difference at points $2°\ 31'$ apart is sensible in the instrument. If the corona is polarized in the same plane, and to precisely the same extent, as the surrounding sky, the two images of it will also appear of their natural color; but if it is either more or less polarized than the surrounding sky these images will be of complementary tints, and the arrangement of the tints will show whether the polarization is radial or confined to a single plane. In order to discriminate between the cases where the corona is polarized to an extent different from the surrounding sky, or not polarized at all, it will be necessary to examine it with the same polariscope, provided with a diaphragm so arranged as to exhibit two fields of view tangent to each other. Then, if the corona is polarized, the two images will be of complementary tints, while if it is not polarized, they will be of their natural color. The experiments I tried were therefore as follows: First I employed the polariscope provided with a diaphragm, and I saw that in each field the sky and the corona were of the same tint, but in the two fields these tints were complementary to each other. Next I employed the polariscope without the diaphragm, and I then saw the sky of its natural color, and the two images of the corona also of their natural color. Clearly, the inference to be drawn from these observations is that, so far as the instrument was capable of determining, the light from the sky and that from the corona were polarized to the same extent; and knowing that the polarization of the sky is produced in our own atmosphere,* I infer that that of the corona had the same origin, and there-

* It may be objected that under the circumstances of a total eclipse we do not know that the polarization of the sky is produced in our atmosphere, because the light of the sky will then be principally due to the corona, and if the light of the latter is polarized that of the former must also be so. To this I reply that the quantitative observations made at Syracuse by Mr. G. Griffith, of the English Expedition, show that the amount of polarization increased from the moon's center outward; a fact which can only be accounted for by supposing the polarization to be effected in our atmosphere.

fore that when the light was emitted from the corona it was not polarized at all. As the tints were faint it was difficult to determine the plane or planes of polarization, and I could not spare time for the attempt.

Dropping the polariscope, I sprang to the spectroscope, and Captain Tupman directed it to the corona. I at once saw a green line, but the wind had blown out the lantern which illuminated the micrometer scale, and, in order to determine the position of the line, I seized my second lantern, which was standing in a sheltered place, held it to the spectroscope, glanced in, saw that the reading was about the same as at Des Moines in 1869, and before I could determine it accurately the wind blew out this lantern also, and I was deprived of all means of making exact measures. However, there cannot be the slightest doubt that the line in question was the now famous 1474, whose wave length is 531.6 millionths of a millimeter. Captain Tupman then directed the spectroscope to many different parts of the corona, and wherever the light was sufficiently bright to show anything I saw the same green line. It is difficult to say precisely how far I traced it from the sun, but certainly to a distance not less than from ten to fifteen minutes. Once I saw two other fainter green lines, of a less degree of refrangibility, which I am pretty confident also belonged to the corona. In addition to these, I several times saw a complete hydrogen spectrum, and on each occasion, supposing it to be due to a prominence, I taxed Captain Tupman with having the needle point of the finder near one of them. Once or twice he admitted that such was the case, but in one or two other instances he denied it. Feeling certain that the lines were produced by prominences, I paid little attention to the circumstance at the time; but on talking over the subject with the Captain afterward, he assured me that on at least one occasion I accused him of having the pointer near prominences when such was not the case. This puzzled me considerably, but after a little reflection I hit upon what I think is the true explanation. The slit of the spectroscope had a length of 0.20 of an inch, which, with the telescope employed, would give a field of view 15′ 46″ high. Hence, when the slit was radial to the sun, one end of it might easily be upon a prominence when the needle point in the finder was eight minutes distant from it. During the last few seconds of totality the thin cloud covering the sun became nearly dissipated, and the faint, continuous spectrum of the corona became visible, but before there was time to examine it the totality was over. Notwithstanding the evidence of the chronometer, I could scarcely believe it had lasted one hundred and two seconds. It seemed to me but a moment, and I felt far from satisfied with what I had accomplished. The high wind and the thin cloud over the sun placed me at a great disadvantage, and prevented me from doing much that would have been easily within my grasp under more favorable circumstances.

Five minutes after the totality was over the sky in the neighborhood of the sun became perfectly clear and remained so till the last contact, which I observed at $2^h\ 19^m\ 0^s.0$. It will be noticed that this time is considerably earlier than that given by Professors Hall and Eastman, but, unless I made a mistake of ten seconds in reading the chronometer, I am unable to explain the cause of the difference. The wind had gone down, so that my telescope was as steady as the ground on which it stood; the definition was admirable, the power 65½, and I left the eye-piece under the impression that I had recorded the contact perhaps a little too late.

I believe the following table contains all the times of contact observed at Syracuse. The different columns explain themselves. The adopted local mean time depends upon the correction derived from my own observations for the chronometer Negus 1115. Professor Hall's observations to determine the error of the chronometer Negus 1228 would make all these times $0^s.5$ earlier.

Times of Contact between the Limbs of the Sun and Moon, observed at Syracuse, Sicily, during the Total Solar Eclipse of December 22, 1870.

* Probably there was a mistake of 10^s in reading the chronometer, and this should be $3^h\ 21^m\ 55^s.7$.

Having thus stated the facts, it only remains to consider what light they throw upon solar physics and the phenomena exhibited during eclipses. This we will now proceed to do.

Origin of the Bright Line seen along the Projection of the Moon's Limb upon the Solar Disk in Photographs of Eclipses.—This line seems to have been observed upon all photographs of solar eclipses hitherto taken, and its cause has been the subject of much discussion, in which such eminent men as Mr. Airy, Professor Challis, and Mr. De La Rue have participated. After the eclipse of August, 1869, Professor Henry Morton examined the question, and made some experiments which showed pretty conclusively that the phenomenon is a chemical effect produced in developing the photograph;* while, on the other hand, Dr. Edward Curtis, in his report on the same eclipse,† described other experiments tending to show that it is due to diffraction, and this view he further supported by a note from Dr. F. A. P. Barnard, in which an attempt is made to show that such a bright line was to be expected as a consequence of the undulatory theory of light. Finally, in March, 1870, Professor Edward C. Pickering made a critical examination of Dr. Barnard's theory, and showed most conclusively from Fresnel's equations that diffraction was not capable of producing the effect which had been attributed to it.‡ Under these circumstances the inquiry naturally arose whether or not the line was visible to the eye during the progress of an eclipse. Here again the evidence was contradictory, Professor Stephen Alexander affirming that he saw it in 1831, and again at Labrador in July, 1860,§ while Professor Smith was unable to detect it in August, 1869. I therefore made it an object of special attention during the eclipse of last December, and, as already stated, I failed to find it. On the whole, I think we are entitled to conclude that the line has no real existence during an eclipse, and that Professor Morton's explanation of its presence on the photographs is the true one.

Is the Light of the Corona Polarized prior to entering the Earth's Atmosphere?—As already stated, my observations tend to answer this question in the negative; but the evidence afforded by other observers is so conflicting that the matter cannot be regarded as settled, and must be an object of further investigation in future eclipses.

Spectrum of the Corona.—All parts of the corona which are sufficiently near the sun give a faint but abso-

lutely continuous spectrum, crossed by a single bright line, whose wave length is 531.6 millionths of a millimeter; and as the spectroscope is moved outward from the sun the light gradually vanishes, the continuous spectrum disappearing first, and afterward the bright line. Judging from Professor Young's observations in August, 1869, and from Father Denza's and my own in December, 1870, I feel pretty certain that some parts of the corona give in addition two other bright lines in the green, which are fainter and less refrangible than that whose wave length is 531.6. The origin of the faint continuous spectrum I attribute mostly to the presence of a little comparatively cool hydrogen in those parts of the corona nearest the sun, but it may also be partially due to the substance which gives the bright line. This latter substance I am inclined to think is most probably incandescent vapor of iron, but it would not be surprising if it turned out to be a new element.

Physical Constitution of the Corona.—That the corona is partially self-luminous, emitting light whose wave length is 531.6, is now universally conceded; but at least one high authority seems to hold the opinion that the self-luminous portion does not extend more than from two to six minutes above the surface of the sun, and that all parts of the corona outside of that limit are produced by means of reflection taking place at some point not definitely specified. Let us examine this theory. If there is any reflection in the case it must happen in one of three places, namely: 1. In the earth's atmosphere, under which term I include a space extending not more than one hundred miles from the earth's surface; 2. Between the upper limit of the earth's atmosphere and the moon; or 3. In the neighborhood of the sun.

Before considering where the reflection takes place, it will be well to comprehend clearly the circumstances under which reflection is possible. Fortunately, on this point the experiments of Professor Tyndall are perfectly decisive. By passing a powerfully condensed beam of electric light through his experimental tubes he found that no matter whether they were filled with air, gas, or vapor, so long as they contained neither dust, motes, nor other solid or liquid particles, they scattered no light, and it was only when such particles were produced within them that the presence of the electric beam became sensible.* We are therefore certain that air, and many other gases and vapors—probably all matter in the gaseous state—is absolutely incapable of reflecting any light whatever. Thus the theory that twilight is partly due to the reflection of the sun's rays by the atmosphere falls to the ground, and we learn that the only reflecting agents are impalpable dust and liquid particles. Hence, the duration of twilight gives us a measure, not of the height of the earth's atmosphere, but of the height to which dust and liquid particles extend in that atmosphere. We shall have occasion to apply this principle presently.

The heat of the oxy-hydrogen flame is sufficient to volatilize almost all known substances, but it will not suffice to render any gas incandescent. For that purpose the electric spark must be employed. We are therefore certain that the heat required to produce a gaseous spectrum is far greater than that required to volatilize any of the elements; and as the spectroscope shows that that part of the corona universally admitted to be self-luminous is composed of incandescent gas, we are entitled to conclude, with a degree of probability amounting almost to certainty, that no solid or liquid matter can exist in its neighborhood. But it has been already shown that gaseous matter is incapable of reflecting light, and it therefore follows that no part of the corona can be due to reflection taking place at or near the sun. This view is also supported by the fact that what little polarization is found in the light of the corona seems to be produced in the earth's atmosphere.† Furthermore, as the light of the photosphere exceeds that of the chromosphere at least 500,000 times, if any reflection takes place between the sun and a point, say, one hundred miles above the earth's surface, we should expect the light so reflected to be that of the photosphere, but no photospheric light has ever been detected in any part of the corona. Professor Young has indeed said that the continuous spectrum of the corona is partly due to such light, and has even given reasons to account for the absence of Fraunhofer's lines in it;‡ but nearly two years ago I suggested that this continuous spectrum was probably due to cool hydrogen,§ and lately Mr. Lockyer has succeeded in showing experimentally that this gas when at a comparatively low temperature does yield a continuous spectrum, together with the bright line F, and, if I do not misunderstand him, he also is now of the opinion that it is the cause of the continuous spectrum of the corona.|| On the whole, it seems certain that there is no reflection anywhere between the surface of the sun and the moon's orbit.

---

* See Tyndall's Fragments of Science, pp. 246 and 306.

† It will be observed that no matter whether the light of the corona is polarized near the sun or in the earth's atmosphere, we should expect the polarization to be radial.

|| Nature, Vol. IV, p. 250.

The whole tendency of modern discovery is to show that the earth's atmosphere has a definite upper limit; but, in order to make as strong a case as possible for the theory that part of the corona is produced by reflection taking place between the moon and the earth, we will suppose that it extends to, or beyond, the moon's orbit. Then we may compute the density of the atmosphere which the moon would be capable of gathering about itself as follows: Taking the diameter of the earth to be 7926 miles, that of the moon to be 3963 miles, and the moon's mass to be 0.0114 that of the earth, it can be shown that at an elevation of 6120 miles above the earth's surface terrestrial gravity will be reduced to an equality with that existing at the moon's surface. If we assume that the laws which govern the expansion of gases near the earth's surface still hold at that altitude, Laplace's barometrical formula will give for the atmospheric pressure there $\frac{6}{10^{210}}$ of an inch of mercury,* which will also be the pressure at the moon's surface.

If we let

N = number of particles in a unit of volume of any gas;

M = mass of each particle;

v = velocity of each particle;

then it can be shown from the mechanical theory of gases that, at the same pressure and temperature, both N and Mv^2 are constant for all gases.† It is well known that the luminiferous ether behaves in many respects more like a solid than a gas, and that the vibrations of sound are longitudinal, while those of light are transversal; but, for the sake of getting a rough approximation to the *order* of density of the luminiferous ether, we will assume that this ether is a gas, and that the velocity of light in it is the same function of its v that the velocity of sound in oxygen and hydrogen gas is of their v's. The best authorities give, for the specific gravity of oxygen, 1.1056, and for the velocity of sound in it, 317.0 meters per second; for the specific gravity of hydrogen, 0.0693, and for the velocity of sound in it, 1269.1 meters per second. These numbers give, for oxygen, $\log Mv^2 = 5.0456$; and for hydrogen, $\log Mv^2 = 5.0477$. The mean is, $\log Mv^2 = 5.0466$, which I adopt.‡ In order to avoid all questions of pressure and temperature, I take as the velocity of light the value found by M. Foucault, from experiments made in the Paris Observatory, namely 298,000,000 meters per second.§ Taking air as unity, this gives for the specific gravity of the luminiferous ether $\frac{125}{10^{14}}$; and as air at the earth's surface supports a column of mercury 30 inches high, it will follow that under the same circumstances the ether would suppor a column $\frac{376}{10^{13}}$ inches high. Taking into consideration the fact that the velocity of light found by Foucault in the rooms of the Paris Observatory scarcely differs from that found in space by means of the eclipses of Jupiter's satellites, I think we must admit that the density of the luminiferous ether is not affected by gravity, and that it will probably be the same at the moon's surface as at the earth's surface. Now, comparing the density just found for this ether with that computed for the atmosphere at the moon's surface, it will be seen that the former is 62×10^{197} times greater than the latter!

No one can be more sensible than myself of the very great uncertainty to which these figures are liable; but after making an enormous allowance for the effect of errors, they would still suffice to prove that the moon is not capable of retaining an atmosphere such as ours, even if she had once been provided with it, and that beyond a comparatively short distance from the earth's surface no matter possessing the power of reflecting light can possibly exist, unless moving with a velocity comparable with that of the planets.

We naturally come next to the consideration of Oudeman's theory, which he states thus: "Both the corona and its beams have the same origin as the zodiacal light."|| As the origin of the zodiacal light is one of the greatest enigmas of astronomy, this explanation would be somewhat difficult to understand, were

|| Nature, Vol. III, p. 26.

it not that in another part of his article he attributes its production to "particles which float in the ether" between the earth's atmosphere and the sun, and thus reflect the solar light to us. As already shown, the duration of twilight furnishes an accurate measure of the height above the surface of the earth at which particles capable of reflecting the sunbeams can float, and the result obtained in this way is usually considered to be 45 miles. I am not aware that any observations have ever been made which give a result so great as 100 miles. Employing Laplace's barometrical formula as before, and expressing the density of the air in terms of the height of the column of mercury which it can sustain, I find the density at 45 miles elevation to be 0.0038 of an inch, and at 100 miles $\frac{87}{10^9}$, or 0.000000087, of an inch. As the least of these densities is more than 2300 times greater than that found above for the luminiferous ether, it does not seem possible that particles of any known substance can float in it. If any particles exist they must therefore be moving in orbits about either the moon, the earth, or the sun—in other words, they must be meteoroids. The richest stream of these bodies of which we have any knowledge is that through which the earth passes annually on or about November 13, but the most condensed portion of that stream is only encountered once in thirty-three years. Our last encounter with it was on the night of November 13–14, 1867, and on that occasion, during the thickest of the shower, the officers on duty at this Observatory counted the falling meteors at the rate of 3000 per hour; from which Professor Newcomb found that on an average there was one meteoroid in 900,000 cubic miles of space*. Clearly, even if the stream were increased in density a hundred-fold, the sun-light which it would be capable of reflecting could not produce any continuous illumination however faint. Thus, then, all the facts within our knowledge seem to point to the conclusion that no reflecting substance which can have any influence in the production of the corona exists between the earth's atmosphere and the sun.

Now let us examine the phenomena which are relied upon to prove that the origin of some part of the corona is due to reflection taking place in the earth's atmosphere. These phenomena may be classed as follows: 1. Drawings of the corona of one and the same eclipse made by persons at different places differ from each other greatly. 2. During the eclipse of last December, Professor Peirce, stationed two miles from Catania, Sicily, saw the outer corona tinged rosy-red over the prominences—a place where no intensely heated hydrogen could possibly exist.† 3. During the same eclipse, Professor Young, stationed at Xeres, in Spain, saw the line C, 6′ or 7′ from the sun, far above any possible hydrogen atmosphere;‡ Mr. Perry, also in Spain, saw a hydrogen spectrum 8′ away from the sun;§ and some observer in Spain, ‖ about whom I have not been able to get any definite information, seems to have seen a hydrogen spectrum upon the face of the dark moon itself.

The light here referred to as giving rise to some part of the corona by reflection in the earth's atmosphere, I understand to be that of the chromosphere and corona itself. The theory that direct sun-light might be so reflected was discussed in my report on the eclipse of August, 1869,¶ and it is not necessary to refer to it again at present, more especially as I believe it is now universally admitted that such a theory is entirely untenable.

In reply to the first class of evidence adduced above to prove reflection, I would urge that no reliable deductions can be obtained from the differences existing between drawings made at places some distance apart, because it is well known that fully as great differences are seen in drawings made by persons stationed within a few feet of each other. An excellent illustration of this was furnished during the eclipse of last December. A fleet of one Italian and five English vessels of war were at Aci Reale, on the coast of Sicily, trying to save the English dispatch-vessel Psyche, and many drawings of the corona were made by the officers of these vessels; but, judging from the published account, no two of them were alike. In fact, two sketches made on the deck of the same ship, the Lord Warden, were so different that it could not have been supposed they were intended to represent the same object.** These differences probably arose partly from want of artistic skill, and still more from the bewildering effect of the strange and exciting phenomena of a total eclipse witnessed, perhaps, for the first time. I have seen so many instances of amateurs making

magnificent sketches of celestial phenomena, which could not possibly have existed, that I confess I have little confidence in any delineations of the corona not made by trained observers who were at the same time competent draughtsmen. Furthermore, it is a matter of common experience that whenever a bright object is seen on a dark ground, that object will appear to be surrounded by a greater or less number of very distinct rays. Yet no one imagines these rays to be real. They are purely subjective, and can be made to disappear from the most dazzling object by looking at it through a dark glass, or from a moderately bright object by viewing it through a telescope of low power. That the corona exhibits real rays cannot be doubted, because they have been photographed; but, as it is a bright object on a dark ground, when viewed by the naked eye it will surely be surrounded by some spurious ones also, and therefore no confidence can be placed in the reality of the existence of any *faint* rays which have not been seen by means of a telescope or opera-glass. To recapitulate, the conditions necessary for the production of a trustworthy drawing of the corona are, that the person making it shall be a trained observer and competent draughtsman, and that no details shall be recorded which are not visible through an opera-glass.

Mr. Lockyer, in two very able papers relative to the eclipse of last December, has said that although Mr. Brothers' photographs taken at Syracuse show such vast rifts in the corona, none of these rifts were *seen* by any of our party; and to this statement he appears to attach considerable importance.* I regret to say that he is in error as to the facts. The great rift was seen by Professor Hall, and is mentioned in his report.†

As to the second and third classes of evidence adduced above to prove that part of the corona is due to reflection taking place in the earth's atmosphere, I have only to say that they apply solely to the eclipse of last December, which happened at a time when the heavens were thick with haze and clouds of all kinds, and no one has ever for an instant thought of denying that light passing through such an atmosphere must be more or less reflected. Manifestly these proofs have no application to the case of a clear and transparent sky, and there is not the slightest reason to suppose that the aspect of the corona seen in such a sky would be any more altered by it than that of a nebula, or the moon, seen under the same circumstances.

In view of the evidence which has been discussed, it seems safe to conclude that when the sky is perfectly clear there is nothing between the eye of the observer and the solar surface which can appreciably alter either the appearance or extent of the corona; and under such circumstances, anything seen in it by the aid of a properly adjusted telescope may be confidently received as representing phenomena occurring at the sun; but if the observations are made with the naked eye the real phenomena will almost certainly be more or less complicated by subjective appearances depending upon irradiation.

From the time of Dr. Wyberd in 1652, down to the present moment, there have not been wanting persons who say that the corona exhibits a rotary motion, but, as these statements are expressly contradicted by nearly all observers of known skill, it is not necessary to consider them further here. There still remains another class of phenomena which cannot be dismissed so summarily, because their existence has been affirmed by astronomers of the very highest reputation. I allude to variations in the brightness of the corona, and to rays, beams, or rifts in it. Otto Struve, observing at Lipesk in 1842, found the corona so bright that the naked eye could scarcely endure it. Mr. Airy has been fortunate enough to witness several total eclipses, and he testifies that the corona was much brighter in some of them than in others. The experience of the officers belonging to this Observatory is the same; the corona appeared much brighter in August, 1869, than in December, 1870. The existence of rays, streamers, and rifts in it is a matter of common notoriety. How are these appearances to be explained? Do we know of any other similar phenomena depending upon ascertained causes? I think we do. The sun is surrounded by a red hydrogen atmosphere, which varies in depth, just as the corona does. The outline of this atmosphere is broken by vast protuberances, corresponding to the rays, or streamers, of the corona. These protuberances vary in position, extent, and number, just as the rays or streamers do. And finally, these proturberances are sometimes brighter, sometimes fainter, depending upon the temperature of the hydrogen composing them, just as the rays of the corona vary in brightness. The analogy is complete, and, if we assume that the luminous gas composing the corona is ejected from the sun in the same manner as the red prominences, all the observed facts will be accounted for; even to such an extreme case as that exhibited in the picture made by Mr. Gilman at Sioux City, Iowa, in August, 1869‡—a picture, by the way, of whose accuracy I am convinced. Moist steam issuing

‡ Washington Observations for 1867, Appendix II, plate 12.

from a boiler at the very moderate pressure of fifty pounds per square inch develops torrents of electricity. The best information we possess indicates that the hydrogen of the red prominences is belched forth with a velocity of about one hundred and twenty miles per second, and it does not seem unreasonable to suppose that it may carry with it a little spray. If it does, then, judging from analogy, the friction of this spray against the mouth of the crater from which it is escaping will probably generate electricity in quantities of which we can have simply no conception, and it may very likely play some part in the production of the long streamers of the corona. In conclusion, the theory which I propose may be stated as follows:

When seen in a clear sky, the corona is a purely solar phenomenon, produced by a vast body of self-luminous gas—not improbably incandescent vapor of iron—which envelopes the sun and is erupted from it in the same manner as the red prominences.

Very respectfully,

WM. HARKNESS,
Professor of Mathematics, U. S. Navy.

Rear-Admiral B. F. SANDS, U. S. N.,
Superintendent U. S. Naval Observatory, Washington, D. C.

ADDENDUM A.

Observations of the Sun for Time, made on the Stone Gun-Platform at Syracuse, Sicily, by Professor William Harkness, U. S. N., with the Sextant Stackpole & Brother No. 937, *Mercurial Artificial Horizon Ha.* 1, *and Chronometer T. S. & J. D. Negus No.* 1115.

[NOTE.—The barometer employed was a pocket aneroid, 1.9 inches in diameter, marked L. Casella, London, No. 1128. It was compensated for temperature, and, in order to reduce its observed readings to the corresponding readings of a mercurial barometer at 32° F., it is only necessary to subtract from them 0.12 of an inch.]

ADDENDUM B.

Observations for Latitude, made on the Stone Gun-Platform at Syracuse, Sicily, by Professor William Harkness, U. S. N., with the Sextant Stackpole & Brother No. 937, *Mercurial Artificial Horizon Ha.* 1, *and Chronometer T. S. & J. D. Negus No.* 1115.

[NOTE.—The barometer employed was a pocket aneroid, 1.9 inches in diameter, marked L. Casella, London, No. 1128. It was compensated for temperature, and, in order to reduce its observed readings to the corresponding readings of a mercurial barometer at 32° F., it is only necessary to subtract from them 0.12 of an inch.]

ADDENDUM C.

List of Articles forming part of the Equipment of the Expedition to Syracuse.

1 Achromatic Telescope of 3 inches aperture and 43½ inches focus, equatorially mounted, and provided with the necessary eye-pieces, shade-glasses, dew-cap, caps for reducing aperture of object-glass, counterpoises, adjusting tools, &c.
1 Single-Prism Spectroscope, with an adapter for attaching it to the telescope, shade-glasses for observing spectrum of the sun, and a lantern for illuminating the micrometer scale.
1 Arago Polariscope of double rotation, for use in the hand.
1 Arago Polariscope, and 1 Savart Polariscope, fitted for use with a telescope.
1 Six-inch Sextant, having a thermometer packed in the same case with it.
1 Mercurial Artificial Horizon.
1 Pocket Sextant.
1 Black-glass Artificial Horizon, provided with inclined planes for measuring zenith distances up to 130°.
1 Prismatic Compass.
1 Small Reflecting Level.
2 Pocket Compasses.
1 50-foot Tape-Measure.
1 Binocular Field-Glass.
1 Pocket Telescope, and screw-clip for same.
1 Set of Colored Glasses.
1 Pocket Aneroid Barometer.
2 Pocket Thermometers.
1 Rain-Gauge.
1 Set of Drawing Instruments.
4 Mean-time Box Chronometers.
1 Leather Case, with strap, to carry a box chronometer removed from its gimbals.
1 Box, with lock and leather strap, to carry 4 box chronometers removed from their gimbals.
Pig lead, to be used for counterpoising telescope.
Olive oil for lubricating axes of stand for same.
Soft rags and camel's hair dusting brush for cleaning lenses.
1 Lantern, and ball of wick for same.
Burning-fluid for same, composed of 1 volume of spirits of turpentine mixed with 4 volumes of alcohol.
Candles and candlesticks.
1 Camp-stool.
Twine—coarse, medium, and fine.
Rope.
Wrapping paper.
1 7-foot American boat ensign, and halyards for same.
Crelle's Rechentafeln.
Bremiker's 6-Figure Logarithms.
Bowditch's 5-Figure Logarithms.
4-Figure Logarithms.
Loomis's Practical Astronomy.
Chauvenet's Spherical aud Practical Astronomy.
Chauvenet's Trigonometry.
American Nautical Almanac for 1870.
English Nautical Almanac Circular, No. 12, giving path of the total solar eclipse of December 21–22, 1870.
Celestial Atlas.
Scale of tints for comparison with color of prominences.
English Admiralty Charts:
North Coast of Sicily.
East Coast of Sicily.
Southern Coast of Sicily.
Sardinia to Malta, including Sicily.
Malta and Gozo Islands.
Valetta Harbors, and the Coast Westward to Madalena Point.
Syracuse Harbor.
City and Bay of Palermo.
Blank forms for time, latitude, and spectroscope observations.
Foolscap, letter, and note paper.
Drawing and tracing paper.
Buff-colored paper.
Blotting paper.
Envelopes, assorted sizes.
Ink.
Pens and penholders.
Black lead pencils.
Blue and red pencils.
India rubber.
Paper-cutter.
Sealing-wax and wafers.
1 Small drawing board, ruler, and square.
1 Claw-hammer.
1 Hatchet.
1 Brace and bits.
3 Screw-drivers, assorted sizes.
1 Set of awls, and other small tools, contained in a hollow handle.
1 Pair flat pliers.
1 Pair round pliers.
1 Pair cutting pliers.
Sail-needles.
Screws and nails, assorted sizes.
Wire of assorted sizes.
6 sheets of sand and emery paper, assorted.

ADDENDUM D.

Letter of Captain Tupman, R. M. A., giving an Account of Observations made by him on the Total Solar Eclipse of December 22, 1870, while assisting Professor Harkness at Syracuse.

H. M. S. PRINCE CONSORT,
Malta, December 27, 1870.

MY DEAR PROFESSOR HARKNESS: According to promise, I send you the few remarks I have to make concerning the eclipse, so that you may know exactly whereabouts I kept your spectroscope during the totality.

It is no use my saying anything about your "finder," through which I observed the corona. If I give any details worth publishing you can add a description of the instrument. It struck me when looking at the spots on the sun that it was particularly good.*

At the first contact the telescope was steady, and my time is good.

When we were examining the adjustment of the pointer of the finder with the slit of the spectroscope, I kept the former on the upper cusp of the sun's crescent. The telescope was vibrating too much in the wind to judge if the adjustment was *very* accurate, but I do not think there was an error of one minute.

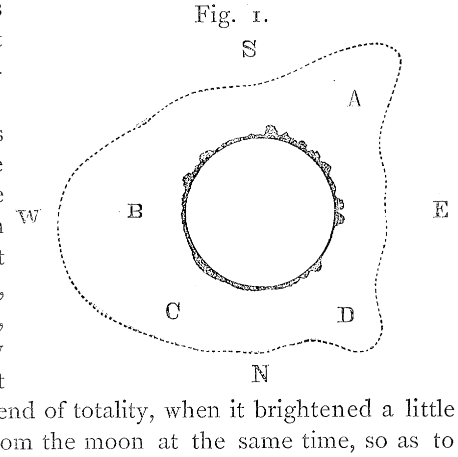
I am unaware of the position in which the slit was placed with respect to the vertical; but I remember that, facing the sun, the eye-telescope of the spectroscope was on the left and inclined very little upward, say fifteen degrees.

I watched the disappearance of the sun without the intervention of any coloring-glass whatever. The definition was perfect. The fine crescent shortened somewhat rapidly, then broke up at either end into several elongated beads of light, and finally disappeared with startling suddenness, when I gave you the time-signal. I could not hear the beats of the chronometer.

Up to this time I had not seen anything of the corona or protuberances, and I do not think the complete disk of the moon was visible; however, I did not take my eye off the disappearing limb of the sun. The ring of prominences and corona appeared as if by magic as the last ray of direct sunlight vanished. The brilliancy of the prominences quite startled me, especially of one a little to the right of the vertex. Their color, and that of the thin ring of light which united them, was a strong apricot pink, a color very difficult to match or describe. It was quite free from any tint of orange or vermilion, and unlike any color of the solar spectrum. The high protuberances appeared like electric lights attached to the limb of the moon. There was a break or interruption in the colored ring in the right lower quadrant, some twenty degrees long, between two not very conspicuous prominences, D., Fig. 1.

The body of the moon was considerably illuminated with a greenish-gray tint, similar to the *lumiere cendree* seen at new moon. I have no doubt the irregularities of the lunar surface might have been seen. The moon was not so dark as the sky beyond the corona, of which I had an extensive view from the size of the field.†

Fig. 1.



The first part of the corona that attracted my attention was a ray, or enlargement in the right upper quadrant, a little to the right of the very bright protuberance A, (Fig. 1;) but by the time you had done with the polariscope, which could hardly have been ten seconds, the left and lower left parts, B to C, were the largest and brightest, and so they remained until near the end of totality, when the part D, in the right lower quadrant, almost, if not quite, rivaled them. The ray D did not enlarge suddenly, but very gradually indeed. The upper part of the corona was throughout the faintest. The extreme right was also faint until quite at the end of totality, when it brightened a little No part increased in brilliancy without extending itself farther from the moon at the same time, so as to become a more or less pointed ray. I do not think any part of the corona extended farther than twenty-five minutes from the limb of the moon; no part was less than ten minutes, if so little.

* The finder attached to my telescope has an object-glass of 1.20 inches aperture, and 8.78 inches focal distance. The eye-piece used by Captain Tupman produced a power of 10 diameters. (W. H.)

† The field of view was 3° 15′ in diameter. (W. H.)

Of the *structure* of the corona I have the liveliest recollection. It was made up entirely of fine black lines, (that is, black enough to be distinctly visible,) on a white background, which commenced imperceptibly at a short distance from the chromosphere, and went off into the sky beyond. They were continuous and uniform, but unequally distinct and unequally distributed, although close together everywhere. There were no curved or crossed lines, or lines radiating from any other point.

The corona had no definite boundary. With the exception of the clearly-defined limit of the red flame-ring there was no other line of demarkation regularly or irregularly parallel to the moon's limb. It was white without a trace of any other color, and less intense than a bright white cloud, except at the base, which was very bright. The intensity diminished rapidly to a distance of five or six minutes, remained nearly uniform to near the outer limit, then faded off rather suddenly, although the unequal extension of the different parts gave it the appearance, as a whole, of fading off much more gradually. There was nothing *geometric* in its form, and the brighter portions, which were invariably those that extended the farthest, did not appear to have any relation of position with the prominences. The outer limits exhibited no coruscations, but faded off in the same uniform radial manner all round.

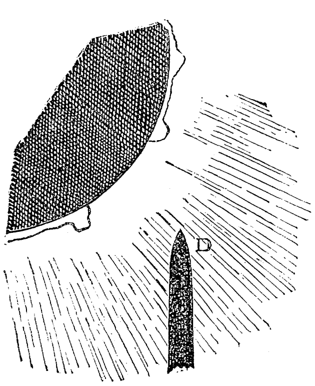
It is quite inconceivable that the corona could have presented the appearance it did to me if it be an atmosphere surrounding the sun to a distance of twenty-five or thirty minutes. My impression is that I was looking into a hollow cylinder of light, the inner surface of which was projected flatly on the plane perpendicular to the line of sight or axis. The change in the form and intensity of parts of the corona also seemed incompatible with its belonging to the sun.

I hardly feel justified in making a drawing, for, having concentrated my attention on keeping the pointer in the most favorable position for the spectroscope work, I did not make any estimations of angles of position, or of the extent or relative intensities of different parts. I chose the brightest parts, and remember whereabouts they were—but not exactly. Besides, my head was inclined considerably to my left, and my estimation of the position of the vertex may be considerably in error; but I am certain that the remarkably bright protuberance I noticed was very near the south point of the moon, then twenty-six and a half degrees to the right of the vertex.*

You will remember that during the partial phase we looked for a line of brighter light on the sun parallel to the limb of the moon. I once or twice fancied something of the kind, but the immediate contrast would account for it. I think it was with a power of eighty or ninety, with fair definition.† I also attentively observed the cusps and the limb of the moon. It would be difficult to imagine anything more striking than the extreme sharpness and *cleanness* with which the light was cut off. The irregularities of the lunar surface were projected very sharply on the sun, affording ocular demonstration of the absence of any atmosphere on the moon.

I endeavored to keep the pointer at a distance of eight or ten minutes from the ring of prominences; but, the vibration of the telescope being about ten minutes on either side, the pointer oscillated between the limb of the moon and the outer part of the corona. I first placed it in the middle of the bright part B, (Fig. 1,) and gradually moved it down to C, and eventually on to D. Once I moved it from B right across to A; but as you then said you could see nothing I quickly went back to B. While examining the part D, the pointer remained very steady for several seconds opposite the middle of the interruption in the ring of prominences, the extreme point making about an equilateral triangle with the terminal protuberances, (Fig. 2.)

Fig. 2.



Of the ninety-five to one hundred seconds that you observed the spectrum the pointer was not ten near the ring of prominences. The spectrum of the chromosphere may have been very often visible when the silt was normal to the limb. From your exclamations at the time I know that the outer limit of the corona gave a *green* line, and it seems to me a most fortunate circumstance that the slit was open to the right extent.

The limb of the sun re-appeared very suddenly, and I at once noted the time, for which I had to put my face very close to the chronometer.

* Captain Tupman sent me a colored drawing which is reproduced in Plate I; except that the sky is there represented somewhat lighter, and the body of the moon somewhat darker, than in the original. (W. H.)

† The magnifying power was 65½ diameters. (W. H.)

The following are the times I noted by Negus 1115:*

	h.	m.	s.
First contact	11	35	30
Disappearance of the sun	1	0	9.5
Reappearance of the sun	1	1	55
Last contact	not observed.		

At Malta the first and last contacts were observed by M. Barthet, with an astronomical telescope of about two inches aperture, as follows:

	h.	m.	s.	
First contact	0	34	12	Valletta mean time.
Last contact	3	18	50	

The position of his observatory is 38 seconds of latitude north, and 0.6 second (of arc) of longitude west of "Spencer's Monument."† I had computed the time of first contact very accurately from the data in the British Nautical Almanac as $0^h\ 33^m\ 5^s$ for the Monument.

For Syracuse the predicted time of the first contact, computed from the British Nautical Almanac, was about ninety-five seconds too late; by the American Ephemeris only four seconds too late.

For the beginning of totality, the British time was about twenty-one seconds too early; the American about sixteen seconds too late.

The duration of the total phase was accurately predicted as one hundred and six seconds.

For the last contact Agnello's time, computed from British data, was $3^h\ 21^m\ 54^s$, and the observed times ranged from $3^h\ 21^m\ 39^s$ to $3^h\ 21^m\ 59^s$ Syracuse mean time.

I am, etc.,

G. L. TUPMAN,
Captain R. M. A.

* At the time of the eclipse Negus 1115 was $1^h\ 2^m\ 45^s.7$ slow of local mean-time. For a complete list of all the times of contact observed at Syracuse, see page 82. (W. H.)

† This, combined with the geographical determinations of the expedition, gives for the position of M. Barthet's observatory, atitude 35° 53′ 37″ north, longitude $0^h\ 58^m\ 4^s.5$ east of Greenwich. (W. H.)

REPORT

OF

PROFESSOR J. R. EASTMAN, U. S. N.

REPORT OF PROFESSOR J. R. EASTMAN, U. S. N.

UNITED STATES NAVAL OBSERVATORY,
Washington, D. C., March 1, 1871.

COMMODORE: I have the honor to present to you, in accordance with the orders of the Honorable Secretary of the Navy, the following report of my observations of the total solar eclipse at Syracuse, Sicily, on December 22, 1870.

In accordance with your instructions I provided myself with the following instruments: A telescope, equatorially mounted, by Clark, with an object-glass 3.25 inches in diameter; an aneroid barometer; dry and wet bulb thermometers; an actinometer, a photometer, and a Savart polariscope.

The above instruments are the same, except the photometer and polariscope, that I used in 1869, and are described in the Observatory Report of the Eclipse of August 7, 1869. The photometer is the same as described in that report, except that the tube has been shortened 3.5 inches, in order, if possible, to measure the relative amount of diffused light in the atmosphere during totality. The Savart polariscope was loaned me by Professor Harkness. It is constructed in the usual manner of a plate of quartz, cut obliquely to the axis, and a plate of tourmaline, but is mounted in a cell, and by means of an adapter was made to fit the telescope like an ordinary eye-piece. In London I completed my list of instruments by purchasing a solar and maximum and minimum thermometers, which had been tested at Kew.

All these instruments, but the telescope and polariscope, were a portion of my private collection.

In company with Professors Hall and Harkness, I left New York on the 2d of November, 1870, by the Cunard steamer China, for England, where I was detained two weeks before I could secure passage by steamer from Southampton to Malta. At Malta I was again delayed by the failure of the steamer, on account of a storm, in making her regular trip, but finally reached Syracuse on the 11th December.

The Prefect of Syracuse very kindly offered us our choice of observing stations, and we selected that bastion of the city wall, northwest of the Porta Terra, or gate toward the mainland. By the courtesy of the Prefect and of the Commandant of the Italian troops in Syracuse, we were allowed the use of an artillery store-house in this bastion for sheltering our instruments when not in use, and were not only constantly provided with a sentinel at the store-house gate during our stay in Syracuse, but Colonel Rossi furnished a strong guard on the day of the eclipse to prevent our being annoyed by crowds of idle wonderers from the city.

On unpacking the instruments the aneroid barometer was found to be somewhat damaged, probably owing to the severe usage which the box received when it was forced open by the customs officers in Liverpool.

The errors of the barometer were determined by comparison with another aneroid, and by frequent comparison I found that its relative indications were tolerably reliable, though utterly useless for absolute determinations except when almost constantly compared with another instrument.

After securing a double-roof protection for the meteorological instruments, I commenced on December 16 a series of observations to determine the normal meteorological conditions, as a standard with which to compare the changes that might occur during the eclipse.

I selected as my station for observing the eclipse the Stone Gun-Platform, 36⅔ yards south of the station chosen by Professor Harkness for observations for time. The meteorological instruments were stationed about four yards east of my observing station, the barometer being fifty-two feet above mean half-tide in the harbor of Syracuse.

It may be interesting, as showing something of the climate of Syracuse in December, to present the daily record of the observations, which I have accordingly done in the following tables. In these tables the

readings of the barometer have been corrected only for error in scale reading and for temperature, and the proper corrections have been applied to the readings of the thermometers.

On the 21st there were unmistakable signs of the coming change in the weather. The barometer was unsteady, but gradually falling; the low bank of clouds, of a peculiar ashy hue, that hung over the Malta Channel, threatened wind from the S. W. or W., and during the entire day Etna was wrapped in a heavy mass of cumulus clouds. At 1^h a. m. on the 22d, a very light shower came on, with a slight sprinkle of snow, accompanied with lightning and thunder. At 7^h a. m. the clouds were quite dense near the horizon, but were clearing away near the zenith. The clouds seemed to condense near the horizon, and by $9^h\ 30^m$ a. m. only light flitting clouds were to be seen at the altitude of the sun. During the morning Etna was visible for about three hours, and it was evident that since the previous morning it had experienced a heavy fall of snow. The barometer was quite low during the morning, and in fact all day, and while Etna was visible in the morning there was an unusually large cloud of smoke or vapor flowing from the crater.

At 11^h a. m., I attempted to make a sketch of the spots on the sun, but the strong wind jarred my telescope so much that I was obliged to give up the idea.

In order to obtain the most and the best work in the shortest time, I arranged the following plan, which, so far as circumstances would permit, I was able to carry out in every respect:

1°. Observe first contact.

2°. Observe with the actinometer until five minutes before the beginning of totality, occasionally examining the edge of the advancing moon.

3°. Observe the time of the beginning of the total phase.

4°. With the polariscope observe—1°. The dark surface of the moon; 2°, the sky near the corona; 3°, the corona, especially the denser portions.

5°. Observe the time of the end of totality.

6°. Observe with the actinometer as before.

7°. Observe the time of last contact.

Mrs. Eastman was, as in 1869, to make the usual meteorological observations, and observe with the photometer at intervals of ten minutes during the progress of the eclipse, and during the total phase to make one observation, if possible, with the photometer, and read the solar thermometer once.

By noon the wind had considerably increased and the flying clouds were increasing in density.

At the time of first contact, though the sky was perfectly clear about the sun, the wind disturbed the telescope so much that I could not get a good image of the sun's limb at the point of contact, and the time of contact, as I observed it, $11^h\ 39^m\ 12^s$, by chronometer Negus 1340, which I used for all time observations on the 22d, must have been several seconds too late.

Soon after first contact I attempted to make some observations with the actinometer, but the increasing and quickly moving clouds prevented my getting more than two good readings, and though I made several subsequent trials at every favorable opportunity during the day, I did not succeed in getting a single complete set of observations.

After the first contact the cloudiness increased quite rapidly, and about twenty minutes before the totality a dense white cloud completely obscured the sun, its increasing proportions threatening to frustrate all our hopes for success. This cloud did not disappear by moving away in a mass, but seemed to melt away from a point in the vicinity of the sun, remains of it completely surrounding the sun until some minutes after totality. About four minutes before the total phase a rift, about three times the diameter of the sun, appeared in this cloud, through which the outline of the sun could be easily traced, and the light cirrus-like clouds that were constantly passing over this space were dense enough to enable me to examine the decreasing cusps of the sun without the aid of the colored shade for the eye-piece.

As the crescent of light gradually decreased the boundary of the aperture in the cloud grew somewhat larger and more distinct, with the sun apparently in the center of this cloud-frame, and the light, fleeting clouds that drifted across the face of the moon became less dense and moved with a lower velocity. After the obscuration of the sun by this cloud the wind increased considerably and blew in fitful gusts, while the chilly sensation, as of going into a deep cavern, came on suddenly and to such an extent that the addition of more clothing failed to counteract its effect. The phenomenon of total obscuration of the solar light was, of course, owing to the apparent difference of the relative diameters of the sun and moon, quite different from that in 1869.

In 1869 the thin crescent faded away very rapidly from the cusps toward the central line, while at the center there was an appreciable breadth of light; but at Syracuse the crescent of the same breadth was at least twice the angular length of that of 1869, and broke up into four pieces, all of them seeming to disappear at the same instant. Just previous to the totality I attached the polariscope by means of the adapter to the telescope and carefully adjusted the focus. The eye-piece connected with the polariscope had a magnifying power of 32, and with this eye-piece I observed the beginning and end of totality.

I noted the time of beginning of totality at $1^h\ 3^m\ 51^s.0$ by chronometer 1340. I immediately turned the telescope upon the dark face of the moon, and saw alternate dark and light bands of nearly equal intensity over the whole surface, but the distinction was a little less marked at the center of the moon. These bands were not changed in distinctness or tint during a complete revolution of the polariscope. I then moved the telescope so as to take successively into the field portions of a belt of the sky outside the visible limits of the corona, extending completely around the moon, but the alternate dark and light bands remained the same in tint, but varied in intensity or distinctness, according to the position of the clouds. Where the sky was nearly clear of clouds the definition of the bands was about the same as on the dark surface of the moon, but the definition was very much improved whenever a denser portion of the cloud was in the field. I then moved the telescope around the moon in such a way as to keep the lower and denser portion of the corona near the middle of the field, with results similar to those derived from the examination of the sky beyond the corona, except that the intensity of the tint of the bands was at its maximum when they were parallel or perpendicular to a tangent to the moon's limb. Once I thought I detected a faint tinge of green in the bands, but I was not able to see it again. I also saw a faint but decided red tinge in the bands over what I at first took to be a very dense portion of the corona, on the southwest limb of the sun, but on more careful scrutiny it proved to be a cloud moving easterly. I then turned the telescope for an instant to the bright edge of a cloud near the westerly limb of the sun, and there saw distinct traces of

color in the bands, though the tints were very faint. As it was now nearly time for the end of totality, I brought that portion of the moon's limb where the light of the sun would re-appear into the center of the field, and, during the few remaining seconds, carefully studied the appearance of the corona and the most conspicuous protuberance.

The structure of the corona appeared essentially the same as in 1869, and consisted of three distinct portions.

That portion next the edge of the moon, in many cases nearly obscured by the low and quite continuous range of protuberances which stretched along the limb of the sun for about 150°, was nearly white and resembled the denser portions of nebulæ. It seemed to be concentric with the sun, and I estimated its height, at the point near the large protuberance, at about one minute. The height of the next portion above the limb of the moon was about six minutes, and it had a decided radial structure, especially near the outer limit. Its color was silvery white. This portion seemed to be concentric with the sun, and its form was quite symmetrical, showing no change whatever in its outline in the vicinity of the protuberances.

The third and outer portion of the corona, on the western limb of the sun, consisted of three projections of light striated, or of a radial structure, resembling the short bands of streamers that are frequently seen rising from the auroral arch. One of these projections on the northwest limb of the sun was quite small, extending not more than five minutes above the limit of the second portion of the corona. The others, one on the southwest and one on the northwest limb of the sun, attained an altitude of about nine minutes above the second division of the corona.

The projections from the main portion of the corona were a silvery or grayish-white color, and the light was steady without any flickering.

Near the extremities of these projections they resembled very much the appearance of the sunlight as it passes through the interstices of the clouds near sunrise or sunset. The only protuberance which I noted carefully enough to enable me to sketch its position and outline, was located a little to the north of the point where the sun's light re-appeared. In form it resembled a mushroom, or the conventional representation of a waterspout, its outer limit being about two minutes above the limb of the moon. Its northern limit was quite smooth and regular, while the southern edge was rough and jagged, looking as if a strong current of wind was sweeping the lighter portions of its mass to the southward, and showing these rough edges and floating, irregular filaments in projection. The color of the southern end of this protuberance was a lighter pink than the main portion of the mass, or than the low range of protuberances, which I had no time to examine further than to note their color and general outline.

The end of totality was preceded by an increasing glow near the limb of the moon, south of the large protuberance, and announced by the bursting forth of a mass of light, shaped like the apex of a sugar-loaf, which spread north and south along the edge of the moon like a flash of lightning. This phenomenon I noted at $1^{h}\ 5^{m}\ 32^{s}.5$. At the end of totality I immediately finished my sketch of the corona and protuberances, and completed my fragmentary notes of the phenomena.

About fifteen seconds before the end of totality, the murmurs and exclamations of the people who had crowded into the open space between our guards and the prison, became so loud that I could not hear the beat of my chronometer, and Mrs. Eastman abandoned her general observations to count the second beats of the chronometer aloud.

During totality I felt some hard substance strike my face several times, and Mrs. Eastman noticed the fall of a few small hail-stones at that time. At about fifteen seconds before the end of totality the clouds and haze had nearly disappeared about the sun, and in five minutes afterward it was perfectly clear. Mrs. Eastman succeeded with all her contemplated observations except with the photometer, and only by her assistance was I enabled to observe the time of the end of totality.

Before totality the flying clouds so interfered with every set of observations with the photometer that their value was entirely destroyed, and during totality the whole aperture of the instrument did not admit light enough to illuminate the image at the base of the tube. After totality, the flying clouds, though they obscured the sun but a few minutes at a time, destroyed the value of the observations for the purposes of comparison, and they have therefore been entirely omitted.

The clouds gradually decreased, and about the time of last contact had entirely disappeared in the vicinity of the sun, while the wind had nearly died away. I observed the last contact with great care and very accurately, I think, at $2^{h}\ 22^{m}\ 53^{s}.5$.

The meteorological observations during the day, as made by Mrs. Eastman, are shown in the following table, where all the scale readings have been corrected when necessary, and the barometer readings have been corrected for temperature.

Maximum temperature from December 21 17^h to December 22 16^h . . . . 61°.5
Minimum temperature from December 21 17^h to December 22 16^h . . . . 52°.0
Amount of rain and snow on the morning of the 22d . . . . 0 .02 inch.

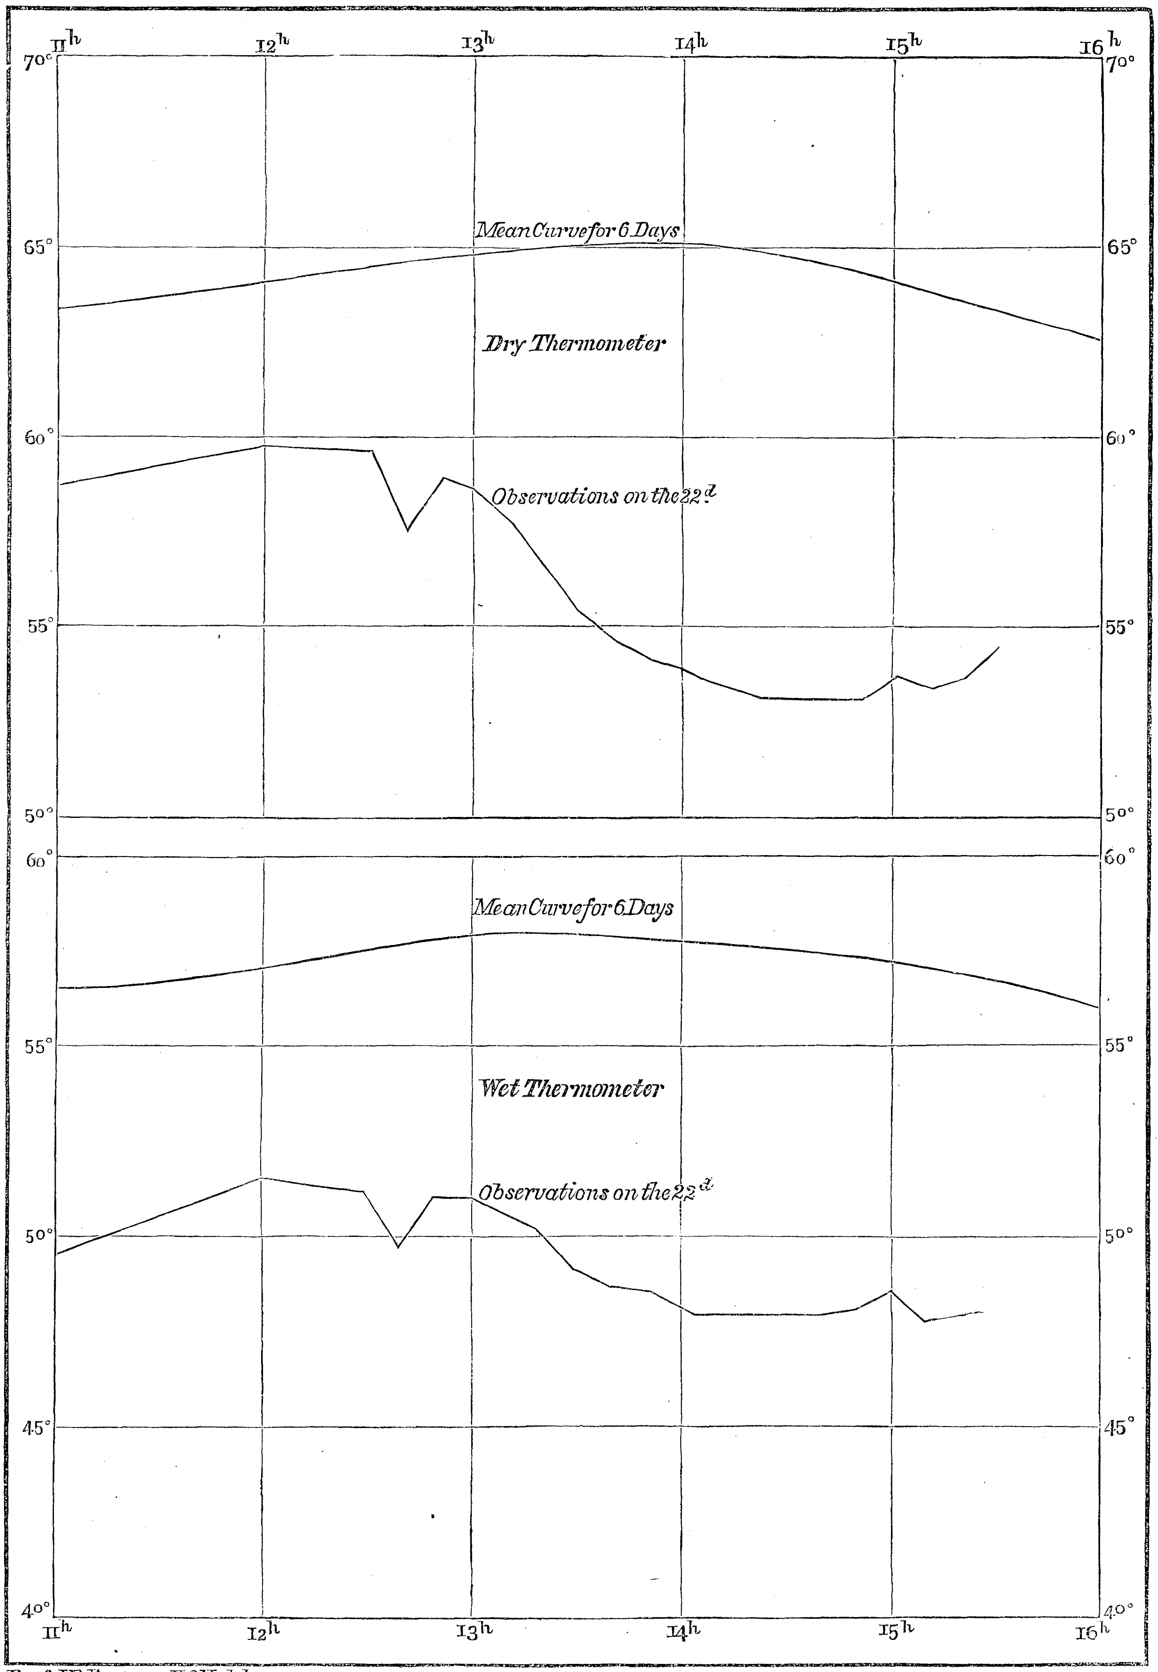
Fig. 1 represents the mean curves of the dry and wet thermometers for six days and the observations on the 22d.

Fig. 2 represents the mean curve of the solar thermometer for six days and the observations on the 22d.

On the morning of the 22d, my chronometer No. 1340 was compared with No. 1115, used by Professor Harkness, and I also compared them after the observation of the last contact. The following are the results:

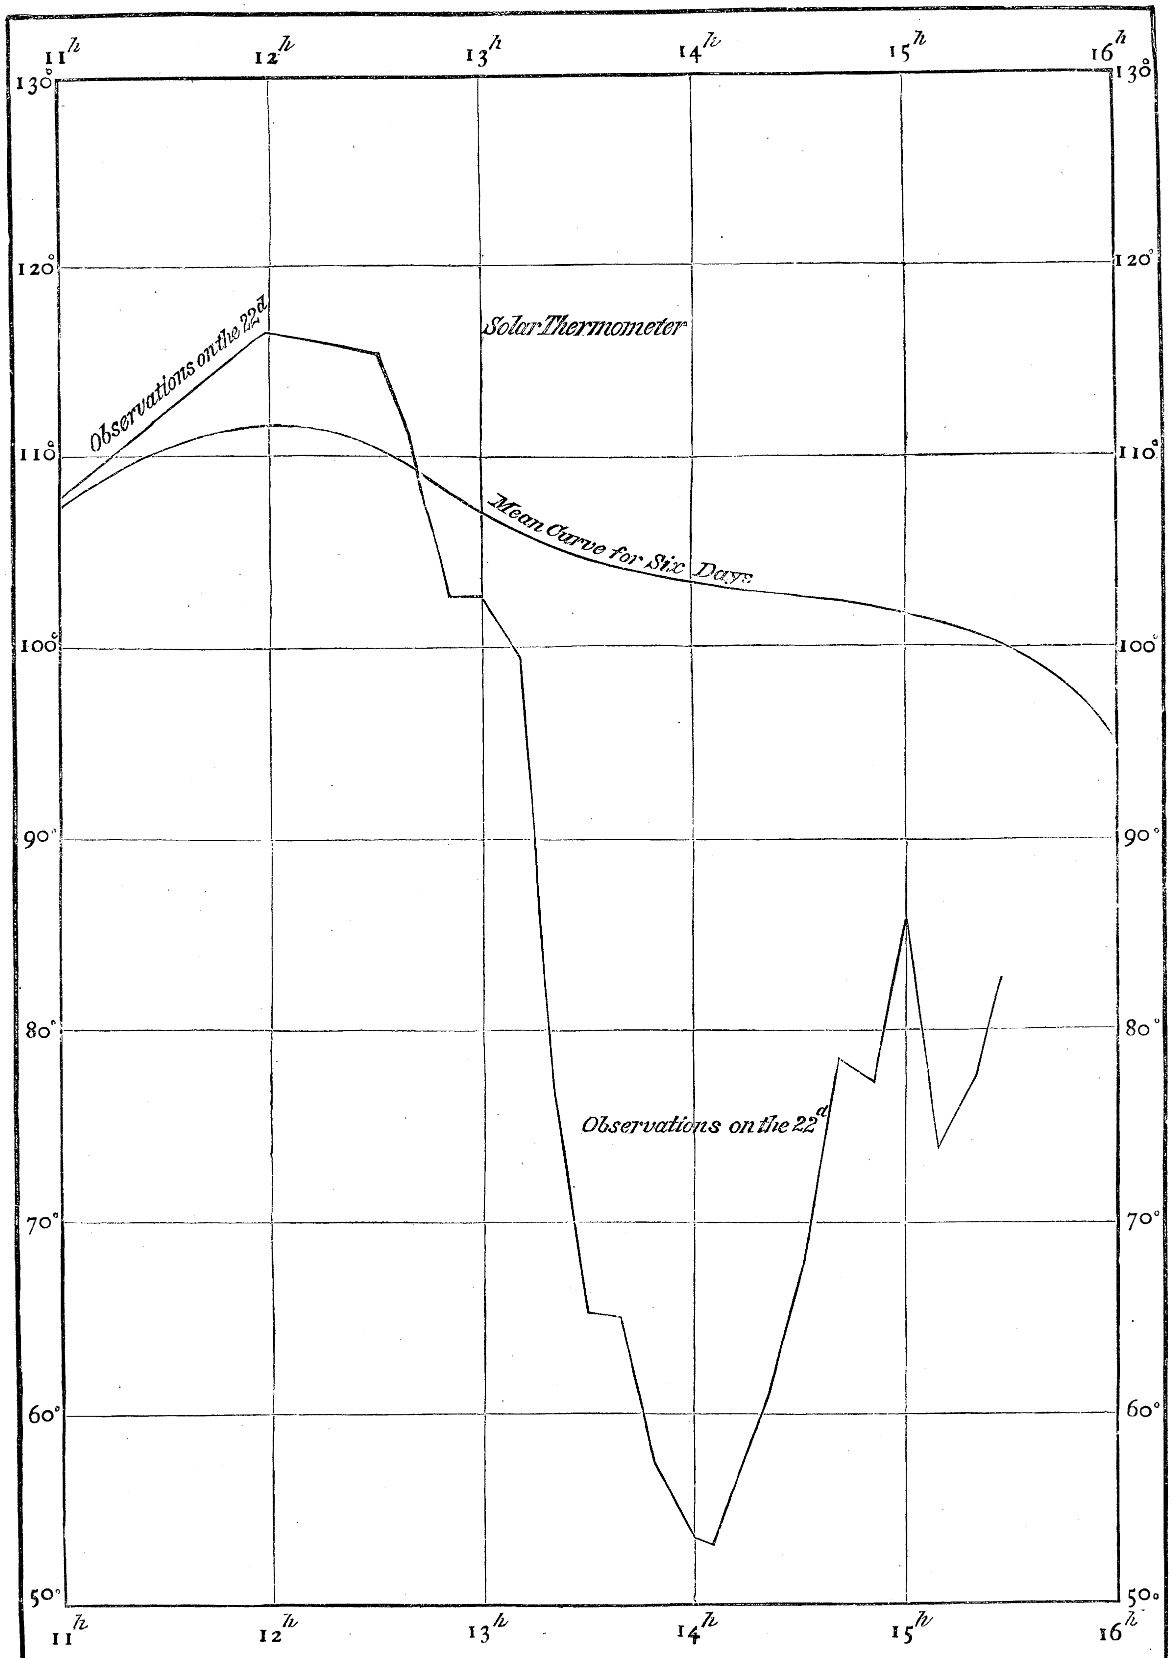
No. 1340.			No. 1115.		
h.	m.	s.	h.	m.	s.
9	5	39.2	9	2	0
2	32	39.8	2	29	0

Fig. 1.



Prof. J. R. Eastman, U. S. N. del.

Fig. 2.



Prof. J. R. Eastman U. S. N. del.

From Professor Harkness's observations, No. 1115 was found to be $1^h\ 2^m\ 45^s.7$ slow of local mean time at both the morning and afternoon comparisons; hence the errors of No. 1340 when the comparisons were made were $-0^h\ 59^m\ 6^s.5$ and $-0^h\ 59^m\ 5^s.9$, with a gaining rate of $0^s.11$ an hour. Applying the corrections deduced from the above data to the observed times of contact, and comparing the results with the times computed by Professor Hall from the data in the American Nautical Almanac, assuming the latitude of Syracuse to be $+37°\ 3'\ 53''$ and the longitude $-6^h\ 9^m\ 25^s.6$ from Washington, we have the following table:

	Prof. Hall's Computed Time.			Observed Time.			C.—O.
	h.	m.	s.	h.	m.	s.	s.
First contact	0	38	15.8	0	38	18.2	— 2.4
Beginning of totality . .	2	3	1.8	2	2	57.1	+ 4.7
End of totality	2	4	43.0	2	4	38.6	+ 4.4
Last contact	3	22	5.1	3	21	59.4	+ 5.7

The accompanying sketch was made from the appearance of the phenomena in the telescope when the principal prominence was near the center of the field, just before the end of totality, and to avoid any chance for confusion the sketch has been finished in the inverted position in which it was seen in the telescope.

On the night of the 12th December I saw a few meteors, and the observations are given in Addendum A.

While in Malta I was greatly indebted to Mr. Lyell T. Adams, the American Consul, who spared no pains to make our forced stay an agreeable one; to Captain G. L. Tupman, of the English Navy, and Mr. Rosenbusch for many courtesies; and to Rear-Admiral Hastings R. Yelverton, commanding the English fleet in the Mediterranean, who very kindly offered to carry us to Syracuse in his dispatch-boat if the regular steamer did not go in season.

At Syracuse the American Consular Agent, Signor Nunzio Stella, was very assiduous in his courteous attentions to our party and rendered us all the aid we could desire, as did also Mr. Frederick Behn, the American Consul at Messina. I am also under obligations to the Prefect and the Syndic of Syracuse, to Colonel Rossi, Commandant of the King's troops in Syracuse, to Signor Bisani, the English Consul in the city, and to the Syndic of Augusta; in fact, this list might be extended to contain the names of all the government officials and scientific men whom I met in England or on the continent, since all manifested a strong desire to aid us officially and socially whenever an opportunity occurred.

As soon as the storm which came on after the eclipse had subsided, I left Sicily for the continent and reached Washington on the 18th February, 1871.

Very respectfully, your obedient servant,

J. R. EASTMAN,
Professor of Mathematics, U. S. Navy.

Commodore B. F. SANDS, U. S. N.,
Superintendent U. S. Naval Observatory, Washington, D. C.

ADDENDUM A.

Meteors observed at Syracuse, Sicily, December 12, 1870.

The observations were made from the tower of the "Albergo della Vittoria," and the tracks were recorded on a temporary chart hastily constructed for the occasion.

Only the southern portion of the heavens was mapped on this chart, as I intended to observe to the southward and note only such stars as might be seen by Captain G. L. Tupman at Valetta, Malta.

The time was taken from a pocket-watch, which, by comparison with our chronometers, was found to be fifty-five seconds slow of Syracuse mean time.

The times given in the following table have been reduced to Syracuse mean time.

Besides the meteors whose paths are given I saw thirteen that appeared in the east and the west, but beyond the limits of the chart.

Number.	Magnitude.	Time of Appearance.			Path.							
					Beginning.				End.			
		h.	m.	s.	h.	m.	°	′	h.	m.	°	′
1	3	8	42	25	3	10	− 17	0	2	36	− 23	30
2	4		45	10	2	32	+ 4	30	1	52	− 1	15
3	3	8	59	55	3	32	+ 22	30	3	1	+ 17	30
4	3	9	2	10	2	42	+ 21	30	2	9	+ 17	0
5	2		2	25	2	41	+ 20	0	1	47	+ 12	30
6	4		10	35	3	43	− 12	0	3	18	− 16	30
7	3		21	30	4	37	− 12	0	4	10	− 16	0
8	4		22	25	3	26	+ 7	30	3	22	+ 6	0
9	4		26	0	3	7	+ 1	30	2	28	− 6	0
10	3		35	45	4	0	− 5	30	3	32	− 10	0
11	3		42	40	4	2	+ 2	0	3	35	− 2	0
12	2		48	10	2	10	+ 10	30	1	33	+ 5	0
13	3	9	51	10	2	7	+ 13	30	1	36	+ 9	0

The light from all these meteors was white, but none of them left trains.

Most of them moved rapidly, but as I was observing alone I did not attempt to note the duration of each flight.

J. R. EASTMAN,
Professor of Mathematics, U. S. Navy.

APPENDIX II.

WASHINGTON ZONES.

TABLE OF CONTENTS.

INTRODUCTION.

§ 1.

Soon after the establishment of the Naval Observatory a plan was formed for making an extensive catalogue of stars. An account of this plan may be found at pp. [39] to [42] of the Appendix to the annual volume of the Observatory for 1845. The work was begun in 1846, with three meridian instruments, the Mural and Meridian Circles and the Transit Instrument. The zones observed in 1846, below 30° south, were usually gone over but once, the Mural Circle and Transit Instrument taking alternate belts. Those in following years were gone over twice, and generally with different instruments.

The observations of zones of stars were discontinued in July, 1849, as it was then found that the astronomical force of the Observatory was not sufficient to perform the current and necessary duties of such an institution, and at the same time to complete the vast work of cataloguing stars which had been undertaken. In the mean time the professors in charge of the several instruments had prepared formulæ for the reduction of the zones, had determined and tabulated the various instrumental corrections necessary for making the reductions, and had begun the work of reducing. These reductions, however, were soon interrupted by the detachment from the Observatory of some of the officers, and by the ill-health of others, and nothing further was done until 1859. In that year the reduction of the zone observations was resumed by Mr. James Ferguson, late assistant astronomer, who reduced the zones observed with the Meridian Circle in 1846, and which were published in 1860. In the summer of 1861 copies of all the observations of zones were made under the care of Mr. Ferguson, and they were put into the hands of Dr. B. A. Gould to revise the work already done and complete the reductions. He returned them ready for printing in July, 1867.

The stars embraced in these zones are all in southern declination, and for the most part between the parallels of twenty and forty-five degrees, and in regions where as yet very few of the smaller stars had been observed. The observing-books indicate that a large part of the observations with the Mural Circle were carefully made. It has been decided, therefore, to publish the zones observed with that instrument, and also in a succeeding year those observed with the Transit Instrument, these two instruments having been employed conjointly. The following pages, 1 to 331, contain the observations of the zones observed with the Mural Circle in the years 1846, 1847, 1848, and 1849, with the reductions and the deduced positions of the stars. The declinations were prepared by Professor Coffin, except for a portion of the zones in 1849, as also the reductions to mean of wires for the Transit observations in 1846 and 1847, and the preliminary tables for the right ascensions for the whole period, except the portions involving clock and instrumental corrections.

§ 2.

THE INSTRUMENT.

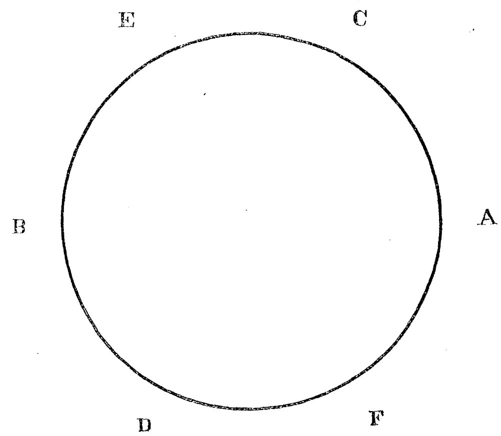
The following description of the Mural Circle, the instrument employed in making the observations, is taken, with slight changes, from the annual volume of the Observatory for 1846:

The Mural Circle was constructed by Troughton & Simms, of London.

During the time of the zone observations it remained in the *east* observing-room, and upon the eastern face of the sandstone pier, to which it was removed in the latter part of 1845. This pier is nine feet four inches high, six feet from north to south, and three feet three inches from east to west. The axis of the instrument reaches entirely across the pier, through an archway of thirty-two inches span and twenty-one inches pitch.

The circle is placed upon the eastern end of the axis, which is sustained in part on friction-rollers supported by counterpoises. It is five feet in diameter. The divisions are upon the periphery of the rim, cut upon a band of gold, and 5′ apart. They are read off by means of six of "Troughton's Reading

Microscopes," mounted firmly upon the face of the pier, and adjusted, as nearly as practicable, 60° from each other. These microscopes are designated in the observations by the letters A, B, C, D, E, F. They are arranged as in the accompanying diagram, A being on the north side of the pier, and the line through the center joining A and B being horizontal. By this arrangement



(the reading for)	B =	(the reading for)	A + 180°
"	C =	"	A + 300°
"	D =	"	A + 120°
"	E =	"	A + 240°
"	F =	"	A + 60°

approximatively.

These microscopes are adjusted, as to focal length, so that five revolutions of the micrometer-screw of each may measure one space, or 5′ of the circle. The micrometer heads are divided into sixty parts—reading, therefore, directly to *seconds*, or, by subdivisions easily made, to *tenths* of seconds. In general, in making readings of the circle, the *seconds* and *parts* are read from each of the six microscopes, and to these are prefixed the *degrees* and *minutes* from A alone. The mean of these six readings constitutes the "Circle Reading."

For illuminating the graduated limb, a lamp is placed behind the pier in a line with the axis of the instrument; the light from this lamp passes through six holes, bored through the pier, directly to the reflectors attached to the several microscopes. In this way a less variable illumination is secured than formerly by means of lamps carried in the hands. The object aimed at has been to have the same illumination for the readings of the circle, both in the observation of a star and in the determination of the "Nadir Point" which is to be employed in its reduction.

The circle is adjusted to a vertical position by means of a plummet suspended on a fine silver wire, with the aid of appendages, attached to the telescope known as "Ramsden's Ghosts," and to its position in the meridian by observations of the transits of circumpolar stars.

The telescope of this instrument has an object-glass of four inches clear aperture, with a focal length of five feet. It is attached to an independent axis, moving within the axis of the circle, and may be moved to any position with reference to the graduations. The ends of the tube, or the cells supporting the object-glass and the micrometer, are firmly clamped to the rim of the circle.

The eye-end of the telescope is furnished with a fixed diaphragm, containing seven vertical wires, designated I, II, III, &c., nearly equidistant, and at an average interval apart of $15^{s}.4$, (in time,) and one horizontal wire, which it is found convenient to call the *fixed wire*. The adjustments of this diaphragm have consisted in placing it in the principal focus of the object-glass—turning it so that an equatorial star will exactly traverse the *fixed wire*—and, the circle being adjusted to an exact vertical position and the telescope directed to the nadir, moving the diaphragm so that the *vertical wire* IV will coincide with its image reflected from a surface of quicksilver and seen by means of the collimating eye-piece.

In connection with the fixed diaphragm is another, movable, with a micrometer-screw, and furnished at the commencement of the year (1846) with one wire or spider's line only. In the latter part of February, in order to adapt the instrument to the work of cataloguing, this diaphragm was furnished with *eight* additional wires parallel to the original one, and distributed on each side of it at distances equivalent to five revolutions of the micrometer-screw. Subsequently the four nearest to the middle or original one were removed, those which remained being respectively *five*, *fifteen*, *fifteen*, *five* revolutions apart. These were changed in May, 1849, to intervals of *five*, *ten*, *ten*, *five* revolutions. In the record of the work in which

they have been employed they are numbered **1**, **2**, **3**, **4**, **5**, in the order of the micrometer-scale, *i. e.*, commencing in the southern part of the field of view. To render available so large an extent of field in declination as is embraced in this system of wires, the eye-piece was also provided with a vertical motion. The adjustment of this diaphragm consists in making *wire* **3** parallel to the *fixed wire*.

The head of the telescope-micrometer is divided into 100 parts, and is usually read to *thousandths* of a revolution. It is adjusted so that when *wire* **3** is moved into coincidence with the *fixed wire*, the micrometer reading shall be nearly $30^{r}.000$, 30^{r}. indicating the notch of the micrometer-scale which is intersected by the *fixed wire*. In making a micrometer reading that notch of the scale is noted which the wire used in the observation has passed.

§ 3.

METHOD OF OBSERVING AND OBSERVERS.

The instrument was clamped at a division of the circle, or midway between two divisions, and the microscopes were read, (on two sets of division when the circle was set between them,) and also the meteorological instruments. These readings were generally repeated several times during the observation of a zone. The transits were observed by the eye and ear method. The bisections for declination were made at one of the transit wires I, II, III, IV, &c., with one of the micrometer wires **1**, **2**, **3**, **4**, **5**. The observations were recorded in blank-books, the form of which is given in the Appendix of the annual volume for 1845, under the heads *O* and *P*. The following notes are taken from one of Professor Coffin's observing-books:

a. "The transit wire on which the micrometer bisection is made is the IV wire if the transits were observed upon it or upon wires both sides of IV; otherwise the wire observed on nearest IV. The exceptions are noted."

b. "The micrometer wire when not noted is wire **3**."

c. "The minute belongs to the first transit wire observed."

The above rules were followed by Professor Coffin in all his observations, and it appears that the other observers followed the same rule with regard to the minute of the transit.

The observers were Professor J. H. C. Coffin, U. S. N., who observed from the beginning until the end of the work in 1849; Lieutenant T. J. Page, U. S. N., who observed from the beginning until January 4, 1848; and Lieutenant Charles Steedman, U. S. N., who observed from December 15, 1847, until June 21, 1849. The initial of the observer is placed at the beginning of the zone together with the date of observation.

The adjustments of the instrument were made by Professor Coffin, who also made the observations for determining the value of a revolution of the telescope micrometer and the corrections of the micrometer wires.

Professor Coffin furnishes the following corrections to be applied to the micrometer readings, derived from the published volumes of the Observatory for the years 1846 to 1850:

1. *Corrections on Account of Eccentricity of the Micrometer-Head.**

Mic. Reading.	Correction.	Mic. Reading.	Correction.	Mic. Reading.	Correction.
.00	$-\ 0^{r}.0000$	.35	$-\ 0^{r}.0029$	.70	$-\ 0^{r}.0001$
.05	05	.40	28	.75	+ 04
.10	10	.45	27	.80	09
.15	15	.50	23	.85	10
.20	20	.55	19	.90	09
.25	24	.60	14	.95	06
.30	— 28	.65	— 08	.00	+ 00

* Washington Astronomical Observations, 1846, Introduction, p. xviii.

2. *Reductions of Wire 𝕭 to Parallelism with the Horizon.*

These are given at transit wire III; the same numerical values answer for V; for II and VI, they are to be multiplied by 2; and for I and VII they are to be multiplied by 3; and the signs changed for V, VI, and VII. The reduction at IV is 0.

3. *Reduction of the other Micrometer Wires to Wire 𝕭.*

These reduce the readings for observations with the several wires to what they would have been if wire 𝕭 had been used.

During 1846 and 1847 wire 𝕮 could not be brought into coincidence with the fixed wire, so that the reductions for it have not been determined; and, therefore, except in the earlier zones of those years, that wire has not been used. In a few of the earlier observations of Lieutenant Steedman he has used a wire which he calls 𝕲, of which there is no account. The declinations derived from observations with these two wires are, therefore, imperfectly determined; so also from observations with wire 𝕴, in zones 158–161 and 178–187.

The periods of the following table are those in which there was no known disturbance of the wires, and the several determinations agree satisfactorily with each other.

1846, April 4 to December 31.

36	135	60	15
38	145	64	16
40	+ 156	+ 69	+ 17

These several reductions, except the first, can readily be combined for any zone for each micrometer and transit wire.

The equatorial intervals of the transit wires from their mean were derived by Professor Coffin from the zone observations in 1846 and 1847 for each 5^r of the field as indicated by the micrometer reading, and the transits in those years reduced by him to the "mean of wires;" but the papers containing tables of these intervals, as well as Dr. Gould's tables for the subsequent years, cannot now be found.

The periods during which the intervals may be regarded as constant are sufficiently indicated by the notes of changes and disturbances of the wires on page VIII.

Dr. Gould's determinations of the reduction of the "mean of wires" to the meridian for the several zones have also been mislaid, so that they appear in the zones only in combination with other reductions.

The observations with the Mural Circle were differential in right ascension; and these reductions could be obtained only by means of right ascensions of stars of comparison, supplied either by observations with the other instruments or by the catalogues of stars. The earlier zones observed with the Mural Circle and Transit Instrument in 1846 unfortunately overlapped on one side only, owing to some misunderstanding as to the declinations at which each instrument should be set; so that the other side of each is almost entirely deficient in common stars. This deficiency has, however, been supplied by observations made subsequently by Professor Yarnall.

§ 4.

In the following tables are collected the clock corrections, with the hourly rates; the observed coincidence of wire **3** with the fixed wire, the adopted values of a revolution of the micrometer-screw, and the readings of the circle for the zenith point. These quantities have been taken from the volumes of the Observatory for the years 1846, 1847, 1848, and 1849.

The clock corrections are copied from the observations with the Meridian Circle. In the copy of the earlier zones prepared for Dr. Gould the quantities m, n, and c, as well as the clock corrections, were taken from the Meridian Circle observations, and were printed before the error was noticed. They do not belong to the Mural Circle zones.

The coincidence of wire **3** with the fixed wire was determined on almost every day of observation from six or eight contacts (alternately on each side) at the vertical wire IV. Interpolated values are inclosed in brackets.

The value of one revolution of the screw of the telescope micrometer was determined by means of the collimating eye-piece and a basin of mercury. The observations will be found given in detail in the Introductions of the several volumes. The values there given are for the middle of the field. Professor Coffin assumed as the value for the part of the field indicated by the micrometer-reading m,

$$R = R_0 + 2\,(m - 30)\,\Delta R$$

and found the following values of ΔR;

In 1846 and 1847,	from 12 determinations,	$\Delta R = + 0^r.0020$
In 1848, before September,	" 2 "	$+ 0^r.0025$
In 1848,	" 2 "	$- 0^r.0022$
In 1849,	" 4 "	$+ 0^r.0010$

Its value would probably be affected whenever the telescope was unclamped from the rim of the circle and moved. This was done January 2 and September 19, 1848, and January 1, 1849.

The determination of the nadir point was made by means of the collimating eye-piece. The telescope being directed downward, the circle was moved by one of the tangent-screws until the fixed wire, illuminated by means of this eye-piece, coincided with its image reflected from a surface of mercury; then the circle reading corrected for runs and errors of division constitutes the nadir point. Each determination consists of several such coincidences and circle readings, the wire and its image being brought into coincidence from opposite sides.

Corrections of Clock.

§ 5.

METHOD OF REDUCTION.

The magnitudes of the stars, the seconds of the observed times of transit in the columns I, II, III, &c., the micrometer readings, the micrometer wires used, and the transit wires at which the bisections were made, have been taken from the observing-books, and the proofs compared directly with them and corrected to agree with the records of the observers. The minutes of the transits have been changed, when necessary, so as to adapt them to the "mean of wires."

The method of reduction, as arranged by Professors Coffin and Hubbard, is nearly the same as that described by Mr. Ferguson in his Introduction to the Meridian Circle Zones of 1846, published in 1860. The differences arise from the different construction of the two instruments.

1. The times of transit of a star were first reduced to the mean of wires, using for each wire the reduction for the zone in the part of the field indicated by the micrometer reading;

T, representing the clock times of transit of the mean of wires;

k, the clock correction at that time;

I, the reduction of the mean of wires to the meridian for the middle of the field, or at 30^r of the micrometer;

M, the reduction to 1850.0 for the right ascension and declination of the middle of the field;

ΔI and ΔM, the variations of I and M for the distance of the star in declination from the middle of the field, or, $-(m - 30^r)$ in terms of the micrometer, m being the micrometer reading;

and putting

$$a_1 = k + M, \qquad a_2 = I + \Delta I + \Delta M$$

the right ascension of the star is

$$a = T + a_1 + a_2$$

The preliminary work consisted in the preparation of tables for each zone containing a_1 for each 10^m of clock-time, and a_2 for each 5 or 10 revolutions of the micrometer, and at such intervals of time as was requisite. The columns a_1 and a_2 were then readily filled by an easy interpolation.

The column a_2, which is printed, includes corrections for erroneous values of k used in the earlier zones in forming the tables of a_1; and in some zones a constant appears to have been added to one and subtracted from the other so that the signs should be uniform.

2. C, representing the first circle reading for a zone;

Z, the zenith point;

r, the refraction for the zenith distance $(C - Z)$ and the first readings of the barometer and thermometer;

M, the reduction to 1850.0 for the declination of the middle of the zone, or 30^r, and the right ascension of its commencement, or an exact 10^m preceding;

m_0 the micrometer reading for coincidence of **3** with the fixed wire; or, in 1849, the reading of **3** to correspond with $Z = 20° \; 0' \; 0''$:

the constant of declination for the zone is

$$D_0 = 38° \; 53' \; 39''.25 - (C - Z) - 62''.75 \, (m_0 - 30^r) - r + M + 30' + n' + n''$$

$30'$ and the arbitrary constants n' and n'' being added so that all the reductions shall have the same sign as D_0. Omitting these, D_0 is the mean declination of wire **3** at the commencement of the zone and for the micrometer reading $30^r.000$. n' and n'' were omitted from the copy prepared for the printing, and the papers containing them are missing.

The micrometer reading for each star was corrected for eccentricity of the micrometer-head, and reduced from the recorded micrometer and transit wires to wire **3** at transit wire IV, and to the meridian by means of the tables, pages IX and X.

m, representing this corrected reading;

$$i = -\left[62''.75 \, (m - 30^r) + 0''.0025 \, (m - 30^r)^2 + 30'\right]$$

A table for each $0^r.01$ of m facilitated the preparation of this column.

ΔC, representing the change in the circle reading C;

Δr, the change of refraction for changes of the barometer and thermometer;

ΔM, the change of M for difference of right ascension;

$\Delta_1 r$, the difference of refraction; and

$\Delta_1 M$, the difference of M, for the distance of the star in declination from the middle of the field, or $-(m - 30^r)$:

$$d_1 = -[\Delta C + \Delta r - \Delta M + n']$$

$$d_2 = -[(R_0 - 62''.75)(m - 30^r) + (\Delta R - 0''.0025)(m - 30^r)^2 + \Delta_1 r - \Delta_1 M + n']$$

ΔR and R_0 are given on pages XI and XIII–XVIII.

The declination of the star is

$$\delta = D_0 + i + d_1 + d_2$$

The preliminary work for each zone consisted in computing D_0 and preparing tables of d_1 for each 10^m of clock-time, and of d_2 for each 5^r or 10^r of m, and at such intervals of time as was requisite. These columns were then readily filled by interpolation.

The columns i and of right ascension and declination include also corrections for errors of exact revolutions of the micrometer, and of minutes or exact seconds in the times of transit, which Dr. Gould, in the thorough scrutiny which he made, detected by comparison with other zones or catalogues. Such cases are noted in the margin. Some of the few errors of the copyist were detected by him in the same way and corrected.

Notes by the observers of doubtful observations are indicated in the text by a ?; but the degree of doubt, as 1^s or 10^s in a transit, or of 1^r of the micrometer, are omitted; so also are notes of other stars seen whose positions were only estimated. The numbers of stars identified in the British Association Catalogue, and in Oeltzen's Catalogue of Argelander's southern zones, which were added by Dr. Gould, are also omitted, as it was inconvenient to print them; and, moreover, these catalogues and the zones being referred to the same epoch, the stars which are common to them may be recognized with little trouble.

The quantities of reduction and the deduced positions of the stars have been printed as in the completed copy returned by Dr. Gould.

It having been decided to publish the Zones observed with the Mural Circle and Transit Instrument, the supervision of the work was put into my hands by Admiral Sands, Superintendent of the Naval Observatory, in April, 1871. It has been my endeavor to give, in the first place, an exact copy of the observations. For this purpose the proofs were compared, as has been already mentioned, with the hand-books of the observers. The results deduced by Dr. Gould, and his notes to the observations, have been printed without any change. A few cases occur where the results will be changed on account of changes in the copy, but in nearly every case the correction will be indicated by a comparison of the notes and the observations. It was also the intention to print the tables of reduction which had been prepared for each zone, but, unfortunately, up to the present time, these tables cannot be found; should they be found hereafter they will be published either with the Transit Zones or in a separate Appendix.

In reading the proofs I have been assisted from page 1 to 57 by Mr. O. Stone, from page 57 to 73 by Mr. Harrison, and from page 96 to the end by Mr. A. N. Skinner.

I am much indebted to Professor J. H. C. Coffin, Superintendent of the Nautical Almanac, for information concerning the Zones, and for assistance in preparing the Introduction.

A. HALL,

Professor of Mathematics, United States Navy.

FEBRUARY 10, 1872.

INDEX OF ZONES.

In the following Index, D denotes the declination of the middle of the zone, and the following columns give the extent in right ascension, and the number of the zone, the page on which it will be found, and the number of stars it contains.

The whole number of observations of stars in these zones is 14,804; of which—

Professor Coffin made 6,796
Lieutenant Page made 4,721
Lieutenant Steedman made 3,287

D = −40° 5′.

ERRATA.

In printing the "seconds of transit" in the zones observed by Lieutenant Page in 1846 the ciphers should have been omitted, as they do not occur in the observing-book. It appears that both Lieutenant Page and Lieutenant Steedman at first were inexperienced in observing transits, and in their earlier zones only the even second was observed.

In the case of Zone 107 several circle readings were omitted by the copyist, and in the single one copied an error of $-20''$ was made in copying the reading of microscope F, thus introducing an error of $-3''.3$ into this circle reading. It is probable that all the declinations of this zone are systematically in error by this amount.

In numbering the zones the number 180 is repeated at the end of Zone 181, and Zone 182 is called 181, and so on to the end.

Page 3, under "Remarks" in the last note, omit the 25.

Pages 11 and 12, under micrometer, for E. W. read F. W., which denotes the fixed wire.

Page 72, for September 24 read September 28.

Pages 173 to 217, under the head of corrections, the 0^h should have been omitted.

REMARKS.

April 6. At 14^h clear; bright moonlight.
April 9. 9^h to 10^h, thin clouds. Suspended work from $10^h 42^m$ to $10^h 50^m$.
(1) 3. Mic. reading assumed as $44^r.592$, to agree with Transit Z., 1846, April 6, and Mural, May 21.
(1) 24. At $15\frac{3}{4}^h$ clouds rising.
(1) 25. Illumination of wires at times very unsteady.

REMARKS.

(3) 39. Min. of T. one smaller than Transit Z., April 13.
(3) 41. Minute assumed as 42 instead of 43.
(3) 48. Transits probably over I and II, and minute 56 instead of 57.

April 14. At 10[h] clouds forming; some stars may have been missed in consequence; missed none that were seen above the 9th mag.
(4) 7. Micrometer reading assumed as 33″.230 instead of 32″.730. (See Zone 2, No. 6.)

REMARKS.

April 15. Very clear.
April 16. Clear, except cloud bank near horizon; wind fresh, causing the lamp to flare, and rendering the illumination of the wires very unsteady; magnitudes consequently doubtful, and several stars missed.

REMARKS.

(12) 49. Mic. reading assumed as 53.r950, not 54r.950.

May 19. Interrupted at times by very faint clouds, barely visible.

(13) 3. Transit over T. VII assumed as 0s.5 instead of 10s.5.

ZONE 13. MAY 19. P. $D_0 = -29° 34' 30''$—Continued.

REMARKS.

May 20. Night clear, bright, and beautiful.

(13) 26. Minutes assumed as 54 instead of 53.

(13) 32. Transit over T. V assumed as 22^s instead of 32^s to agree with Arg. Z. 384 : 23.

(14) 18. Discordant from Transit Zone of same date.

(14) 26. R. A. discordant from Transit Zone of same date.

(14) 28. Min. assumed as 48 instead of 49.

ZONE 14. MAY 20. C. $D_0 = -34° 34' 50''$—Continued.

1846.	h.	s.	s.	s.	s.	s.	° ′ ″	r.

REMARKS.

(16) 54. Assumed an error of 10^r, making micrometer reading $53^r.843$.

(16) 67. Micrometer reading assumed as $28^r.050$ instead of $28^r.850$.

REMARKS.

(18) 1. Transit over T. V assumed as 30ˢ.0, not 28ˢ.0, to agree with Transit, 1846, August 12, and Mural, 1846, August 20.

(18) 3. Differs 5′ in δ from Mural, Aug. 20.

(19) 7. Minutes assumed as 23 instead of 22.

(19) 14. Micrometer reading assumed as 56ʳ.170 not 55ʳ.170.

June 3. Lamp which illuminated the wires frequently extinguished by the wind.

ZONE 19. JUNE 3. P. $D_0 = -30° \; 49' \; 0''$—Continued.

REMARKS.

(19) 99. Micrometer reading assumed as $44^{r}.875$ instead of $39^{r}.875$.

(19) 104. Micrometer reading assumed as $40^{r}.020$ instead of $45^{r}.020$.

June 3, $17^{h}\ 22^{m}$. Wind too fresh; lamp extinguished.

(19) 117. Minutes assumed as 18.

June 4. Hazy about horizon and above the belt; 15^{h}, haze increasing; mags. and transits doubtful.

REMARKS.

June 6. $13^h 30^m$, very clear; $14^h 14^m$, thick clouds.

(22) 7. Micrometer reading assumed as $11^r.062$ instead of $10^r.062$.

June 15. Early part of evening unfavorable; after $14^h 30^m$ beautifully clear.

REMARKS.

June 16, 15^h 25^m. Stopped by clouds.

(23) 9. Mic. reading assumed as $23^r.070$ instead of $24^r.070$.

June 17. Smoky horizon; night unfavorable; first readings of barometer, &c., at 14^h 50^m; 18^h 10^m cloudy.

REMARKS.

June 22. Night unfavorable; stars unsteady; indistinct as if through clouds.
(26) 2. $17^h\ 3^m$, cloudy.
(26) 3. 1st reading of bar., &c., at $16^h\ 55^m$.
(26) 4. 2d reading of bar., &c., at $17^h\ 35^m$.
(27) 10. Minute assumed as 8 instead of 7.
(27) 17. Micrometer reading assumed as $30^r.630$, not $31^r.630$.

ZONE 27. JUNE 24. P. $D_{\circ} = -28° \, 18' \, 20''$—Continued.

REMARKS.

June 24. Microscope examined frequently without perceiving change in the readings.
After 15ʰ passing clouds occasionally.
At 19ʰ apparently very clear, yet only a few very faint stars passed the field in 17ᵐ.
(27) 40. Min. assumed as 9 instead of 11.
(27) 49. Micrometer reading assumed as 39ʳ.380, not 44ʳ.380.
(27) 52. Transit over T. IV assumed as 38ˢ.0, not 40ˢ.0.
(27) 63. Mic. reading assumed as 48ʳ.230 instead of 47ʳ.230.

ZONE 28. JULY 1. C. $D_0 = -29° 34' 0''$.

REMARKS.

(28) 20. Transits over T.'s IV–VI assumed as 55s.0, 23s.0, and 40s.7; not 45s.0, 13s.0, and 30s.7.
(28) 24. Minutes assumed as 8; not 9.
(28) 25. Minutes assumed as 8; not 9.
(28) 27. Transits over T.'s II, III, and V assumed as recorded over T.'s I, II, and IV.
(28) 28. Transit over T. IV assumed as recorded over T. III.
After 16h interrupted by clouds, which rendered the mags. and transits doubtful.

ZONE 29. JULY 7. P. $D_0 = -27° \ 2' \ 50''$.

REMARKS.

July 7, $17^h 20^m$. Stopped by moon-light.
$19^h 30^m$. Belt resumed.
Reading of Bar., &c., at $19^h 30^m$.

(29) 54. Minutes assumed as 10.

(30) 10. Micrometer reading assumed as $49^r.460$; not $44^r.460$.

(31) 8. Transits over T.'s IV and V assumed as $58^s.0$ and $25^s.0$ instead of $48^s.0$ and $15^s.0$.

Zone 31. July 9. P. $D_0 = -25° 48' 0''$—Continued.

REMARKS.

(31) 60. Transit over T. V assumed as recorded over T. VI.

(31) 72. Micrometer reading assumed as 39r.133; not 37r.133.

July 10, 16h 31m. Bright moon-light.

REMARKS.

(37) 69 and 70. Micrometer reading of these two stars assumed to have been interchanged.

(37) 76. Transits over T.'s III and IV assumed as recorded over T.'s II and III.

(37) 80. Transit over T. V assumed as recorded over T. VI.

July 24. Night unfavorable; cloudy horizon; many stars too faint for observation; at times disappearing as if through clouds.

ZONE 38. JULY 24. C. $D_0 = -30° 47' 50''$—Continued.

REMARKS.

(42) 21. Transits over T.'s III and IV assumed as recorded over T.'s II and III.

(42) 27. Micrometer reading assumed as 22ʳ.175, not 26ʳ.175, to agree with Mer. Cir. Z. 1847, Aug. 30; Mural Z. 1848, Aug. 16; and Arg. Z. 220:127 and 308:57.

(42) 37. Transit over T. III assumed as 34ˢ.3, not 31ˢ.3.

REMARKS.

(42) 60. Transit over T. II rejected.

Aug. 11. $19^h 50^m$, interrupted by clouds; $21^h 23^m$, resumed sweep; wind fresh; the appearance of the stars indicate thin clouds, though none are visible; moon bright.

(43) 14. Transit over T. IV. assumed as recorded over T. III.

REMARKS.

Sept. 9. Very clear; reading of Barometer, &c., at 19^{h} 20^{m}; 20^{h} 15^{m}, moved the circle for other observations.

Sept. 13. 19^{h} 29^{m}, found the Micrometer and fixed wires connected by a small fiber; suspended sweeping until it could be removed; previous observations probably impaired by it. Readings of Barometer, &c., at 19^{h} 50^{m}. 22^{h} 59^{m}, hazy; few stars visible.

CORRECTIONS.

Date.		Corr. of Clock.	Hourly rate.	m	n	c	Zenith Point.	Mic. Co.
1846.	h.	s.	s.	s.	s.	s.	° ′ ″	r.
Sept. 15,	22	+ 2.484	− 0.021	− 0.356	+ 0.527	+ 0.022		

REMARKS.

(56) 20. Micrometer reading assumed as 13r.003 instead of 14r.003.

(56) 26. Declination apparently about 30″ too large by Mural and Meridian Circle in 1847.

(56) 29. Transit over T. V assumed as recorded over T. IV, and minutes as 1, not 2.

REMARKS.

(59) 36. γ Piscis Australis. Micrometer reading assumed as $38^r.0$ instead of $37^r.0$.

Sept. 21. Apparently clear; stars unsteady, variable, as if through clouds.

(60) 12. Micrometer reading assumed as $12^r.506$ instead of $17^r.506$.

REMARKS.

(61) 29. Micrometer reading assumed as $15^r.391$ instead of $14^r.391$.

(61) 52. Transits discordant. Those over T.'s II and IV assumed to be 2^s too small.

(61) 56. Transit over T. VI assumed to have been recorded as over T. VII.

(61) 61. Transit assumed as at 2^s, to agree with Mural Z., 1847, and Arg. Z. 245.83.

ZONE 61. SEPTEMBER 23. C. $D_\circ = -29^\circ\ 32'\ 50''$—Continued.

REMARKS.

Oct. 9, $0^h \; 0^m$. Clear; moon bright.

(70) 10. Declination apparently 40″ too large; perhaps micrometer should have been $25^r.196$.

(70) 13. Precedes 12.3^s.

(70) 17. Transits over T.'s IV and V assumed at $10^s.0$ and $27^s.1$ instead of $30^s.0$ and $37^s.1$; and minutes as 40^m, not 39^m.

(70) 18. Transits assumed to have been 10^s later than recorded, to agree with Mural Z., 1847, December 18, and Arg. Z. 315.89.

ZONE 70. OCTOBER 9. C. $D_0 = -25° 47' 20''$—Continued.

REMARKS.

Oct. 26. Clear; stars steady.

(76) 42. Micrometer reading assumed as 23r.989, not 24r.989.

(76) 50. Micrometer reading assumed as 49r.134 instead of 48r.134.

(76) 52. Minutes assumed as 16 instead of 17.

(77) 4. Transit over T. V assumed as 57s.2 instead of 47s.2.

(77) 19. Transits discordant; T. II assumed as recorded over T. III, and T. VI rejected.

ZONE 77. OCTOBER 28. C. $D_0 = -32° \ 3' \ 10''$—Continued.

REMARKS.

Jan. 6. Clear; stars tolerably steady.

(86) 1. Transits over T.'s IV and V assumed as 2^s and $18^s.2$ instead of 52^s and $8^s.2$; and minutes as 4, not 3.

(86) 3. Minutes assumed as 14 instead of 13.

(86) 39. Micrometer reading assumed as $44^r.038$ instead of $43^r.038$.

ZONE 86. JANUARY 6. C. $D_\circ = -30° 10' 0''$—Continued.

REMARKS.

Jan. 22, $4^h 13^m$, clouds forming. Too cold for good transits.

Jan. 27. Moon very bright; magnitudes of the smaller stars doubtful.

(86) 56. Minute assumed as 37.

(88) 6. Transit over T. IV assumed as $20^s.5$, not $26^s.5$.

ZONE 88. JANUARY 27. P. $D_0 = -29° 33' 0''$—Continued.

REMARKS.

(88) 23. Transit over T. VI assumed as recorded over T. IV; and minutes as 58, not 59.

(88) 44. T. II assumed to have been recorded as T. I. If T.'s IV and V were recorded as T.'s V and VI, T=33ˢ.43.

(88) 46. Transit over T. I rejected.

(88) 50. T.'s III–VI are assumed to have been recorded as T.'s II–V.

ZONE 88. JANUARY 27. P. $D_\circ = -29° 33' 0''$—Continued.

REMARKS.

(88) 66. Transits over T.'s III, IV, and V assumed as recorded over T.'s IV, V, and VI.
(88) 68. Micrometer reading assumed as $14^r.925$, not $19^r.925$.
(88) 82. Transit over T. II rejected.

Feb. 1. Moon up at $4^h 20^m$.
(89) 3. Transit over T. II assumed to have been at $48^s.2$.

ZONE 89. FEBRUARY 1. C. $D_\circ = -30^\circ\ 48'\ 0''$—Continued.

REMARKS.

(90) 60. Micrometer reading assumed as 38r.940, not 43r.940.

Feb. 6. Night fine; stars steady.
(91) 17. Transit over T. VII assumed as 37s instead of 47s.
(91) 21. Minutes assumed as 49, not 50.
(91) 22. Minutes assumed as 49, not 50.
(91) 25. Transits discordant; observations over T.'s IV and V assumed as recorded over T.'s III and IV.

ZONE 91. FEBRUARY 6. C. $D_0 = -28° 55' 30.''$—Continued.

REMARKS.

(91) 70. Transit over middle thread assumed to have been at 24^s instead of 34^s.

(91) 71. Transit of Arg. Z. 282, 60, suspected to have been recorded with declination of η Canis Majoris.

ZONE 91. FEBRUARY 6. C. $D_{\circ}=-28°\ 55'\ 30''$—Continued.

REMARKS.

(94) 6. Micrometer reading assumed as 53r.670 instead of 53r.070, to agree with Arg. Z. 350, 92, and 357, 19.

(94) 10. Minutes assumed as 14 instead of 13.

(94) 12. Micrometer reading assumed as 43r.910 instead of 48r.910, to agree with Arg. Z., 350, 114, and 357, 45.

(94) 17. Declination discordant by 2r.5 (= 2′ 36″.8) from Meridian Circle, 1848, December 18, and Arg. Z. 350, 120, and 357, 58.

(94) 24. Micrometer reading assumed as 30r.355, not 29r.355, to agree with Mural Circle, 1848, and Meridian Circle, 1847.

ZONE 94. FEBRUARY 14. P. $D_0 = -27° 3' 0''$—Continued.

REMARKS.

(94) 127. Transit over T. VI assumed as recorded over T. II, to agree with Arg. Z. 352, 107.

(94) 130. Transit over T. VI assumed as recorded over T. VII.

(94) 138. Minutes assumed as 49 instead of 48.

(95) 3. Differs 3′ 30″ in δ from Arg. Z. 353, 7.

(95) 4. Transits discordant; those over T.'s IV and V rejected.

(95) 11. Transits discordant.

(95) 12. Minutes assumed as 5 instead of 6.

ZONE 95. FEBRUARY 23. C. $D_{\circ}=-30^{\circ}\ 11'\ 0''$—Continued.

REMARKS.

(95) 34. Time of transit over T. V assumed as $32^s.5$ instead of $52^s.5$, and transits over T.'s I, III, and IV as recorded over T.'s II, IV, and V.

Feb. 23. Night favorable but cold; $5^h\ 40^m$ to $5^h\ 57^m$, suspended observations; $6^h\ 52^m$ to 7^h, many small stars missed; observations suspended from $7^h\ 2^m$ to $7^h\ 57^m$ and from $9^h\ 7^m$ to $10^h\ 20^m$.

(96) 1. Minutes assumed as 55 instead of 56.

(96) 2. Minutes assumed as 56 instead of 57.

(96) 6. Minutes assumed as 1 instead of 2.

ZONE 96. FEBRUARY 23. C. $D_0 = -30° 11' 0''$—Continued.

REMARKS.

March 5, $8^h 18^m$, instrument disturbed by a blow from the observer's head, occasioning a change in the reading and in the nadir point. Observations suspended from $8^h 25^m$ to $10^h 25^m$. Readings of barometer, &c., at $10^h 20^m$; at 11^h, interrupted by clouds.

(98) 23. Transit over T. VI assumed as $54^s.5$, not $4^s.5$.

(98) 26. Transits over T.'s III and IV assumed as $4^s.5$ and 22^s, not 45^s and $2^s.2$, and minutes as 48, not 49, to agree with Arg. Z. 349, 6, and Brisbane 1390.

([a]) Corr. for runs $=0''.37$.

([b]) Corr. for runs $=0''.37$.

ZONE 98. MARCH 5. P. $D_0 = -27° 40' 50''$—Continued.

REMARKS.

Mar. 10, 7^h 10^m. Interrupted by clouds.

Mar. 18. Hazy; night unfavorable; many stars doubtless obscured by the haze.

(100) 6. Transits over T.'s III, V, and VI assumed as $43^s.8$, $19^s.3$, and $37^s.8$, respectively, and minutes as 6.

(101) 3. Micrometer reading assumed as $39^r.385$, not $44^r.385$.

(101) 15. Transit observation of T. III assumed as $37^s.2$ instead of $39^s.2$; and minutes as 54 instead of 55.

(101) 16. Minutes assumed as 55 instead of 56.

(101) 17. Transit across T. VII assumed at 16^s instead of 26^s.

(101) 18. Minutes assumed at 2 instead of 3.

ZONE 102. MARCH 22. P. $D_0 = -28° 18' 40''$.

REMARKS.

(103) 40. Micrometer reading assumed as 33r.754, not 32r.754.

(103) 51. 53m assumed to belong to next star; this assumed the same as preceding. Differs 1′ in δ from Arg. Z. 363, 79.

(103) 67. Minutes assumed as 20 instead of 21.

(103) 70. Minutes assumed as 34 instead of 33.

ZONE 103. MARCH 24. C. $D_0 = -29° 33' 50''$—Continued.

REMARKS.

(103) 76. Minutes assumed as 41 instead of 42, and transits over T.'s V and VI as recorded over T.'s IV and V, to agree with Arg. Z. 375, 14.

(103) 85. Observed transit over T. VII supposed to be 30ˢ.5 instead of 0ˢ.5.

(103) 104. Transits over T.'s IV, V, and VI assumed as recorded over T.'s III, IV, and V, and minutes as 41, not 42, to agree with Arg. Z. 401, 67, and W. Mer. Cir., April 18.

(103) 113. Transit over T. VI assumed to have been recorded as over T. V.

ZONE 104. APRIL 3. C. $D_0 = -27° 41' 0''$.

CORRECTIONS.

Date.		Corr. of Clock.	Hourly rate.	m	n	c	Zenith Point.	Mic. Co.
1847.	h.	s.	s.	s.	s.	s.	° ′ ″	r.

REMARKS.

(112) 35. Minutes assumed as 59 instead of 58.

(112) 66. Micrometer reading assumed as $43^r.985$ instead of $38^r.985$.

(112) 80. Transit time is evidently 1^s in error.

REMARKS.

May 17, 12h. Night poor; only slight illumination possible; circle reading noted at 67°, but evidently should have been 68°.

(115) 19. Declination about 38″ too large by Mer. C., 1846; Trans., 1849; and Arg. Z. 383 and 404.

[a] Corr. for runs, +0″.07.

REMARKS.

(116) 63. Right ascension 1^m discordant from Arg. 373, 24.

(116) 68. Transits discordant; that over T. V rejected.

(117) 8. Declination 30′ discordant from Arg. Z. 383, 126; and Mural, 1848, May 3.

(117) 20. Transits over T.'s IV and V assumed as recorded over T.'s III and IV; and minutes as 54, not 55.

[a] Corr. for runs, +0″.06.

REMARKS.

(117) 127. a $1^s.4$ in error by Arg. Z. 223, 46, and Mural Circle, 1846, Aug. 13.

(118) 8. Transits over T.'s V and VI assumed as recorded over T.'s IV and V.

(118) 24. Micrometer reading assumed as $25^r.890$, not $35^r.890$.

(118) 26. Transit over T. VI assumed as $57^s.5$, not $37^s.5$, to agree with Mural Circle, 1846, July 7, and Arg. Z. 214, 46.

*This reading has been assumed as too small by 1°, the intervals of the transit threads affording sufficient evidence of the fact. The reading 66° 25′ is adopted, and the correction made in all the subsidiary computations. [Observing book has 66° 24′.]

REMARKS.

(119) 83. Minutes assumed as 9 instead of 10.

(119) 84. Minutes assumed as 11 instead of 10.

(119) 95. The observed time of transit over T. IV is assumed to have been at $0^{s}.7$, not 7^{s}.

[Observing book has 1^{s}.]

ZONE 120. JUNE 17. P. $D_0 = -30°\ 10'\ 50''$.

REMARKS.

(120) 3. Time of transit over T. V assumed to have been at $6^s.3$ instead of $16^s.3$.

(120) 25. Minutes assumed as 47 instead of 48.

(120) 32. Micrometer reading assumed as $53^r.384$ instead of $52^r.384$.

[a] Corr. for runs $+0''.07$.

REMARKS.

June 17, $19^h\ 1^m$ to $19^h\ 45^m$, stopped to rest.

(120) 100. Transit over T. V assumed as recorded over T. VI.

(120) 105. Micrometer reading assumed as $22^r.223$ instead of $20^r.223$.

ZONE 121. JUNE 17. P. $D_0 = -30° 10' 50''$.

REMARKS.

(130) 6. Transit observations very discordant; that of T. V assumed as 5^s instead of 15^s.

(130) 10. Transit over T. II rejected.

(130) 15. Time of transit over T. V assumed as 9^s instead of 19^s.

(130) 21. Right ascension 8^s smaller than by Mural Circle, 1846, August 18, and Arg. Z. 235, 49.

(130) 28. Micrometer reading assumed as $22^r.548$ instead of $22^r.048$.

(130) 34. Transit over T. IV assumed as recorded over T. VI, and minutes at 54, not 53, to agree with Transit Z., 1847, September 4; Arg. Z. 394, 67, 8.

(130) 38. Micrometer reading assumed as $11^r.227$ instead of $10^r.227$.

[a] Corr. for runs +0″.01.

REMARKS.

(131) 66. Transits over T.'s III and IV assumed as recorded over T.'s IV and V, to agree with Mural Z. June 17, and Arg. Z. 245, 15.

(131) 73. Transit over T. III assumed as 34^s instead of 44^s.

REMARKS.

(131) 85. Micrometer reading assumed as $12^r.670$, not $14^r.670$, to agree with Arg. Z. 228, 19; 245, 52; and Mural Z., 1846, September 23.

(131) 92. Transit over T. IV assumed as recorded over T. III.

(131) 100. Transit over T. V. probably recorded over T. IV, to agree with Transit Z., 1846, September 23.

(131) 121. The time of transit over T. IV is assumed as 49^s instead of 54^s.

REMARKS.

(131) 126. Minutes assumed as 15 instead of 14.

(132) 6. Transit observations very discordant.

(132) 24. Transit over T. IV assumed as recorded over T. III, to agree with Arg. Z. 235, 38; 241, 31; and Mer. Cir. Z., 1846.

(132) 25. Transit over T. V assumed as recorded over T. VI, to agree with Arg. Z. 235, 39; 241, 32; and Mer. Cir. Z., 1846.

(132) 26. Transits over T.'s III and V assumed as recorded over T.'s II and IV, to agree with Arg. Z. 235, 40, and Mer. Cir. Z., 1846.

[a] Corr. for runs +0″.08.

REMARKS.

(132) 137. Differs in right ascension 1ˢ.88 from Transit Z., 1846, September 22.

(132) 163. Transit over T. V assumed as 43ˢ, not 4ˢ.3.

(132) 168. Micrometer reading assumed as 39ʳ.930 instead of 44ʳ.930.

(132) 170. Time of transit across middle thread assumed as 45ˢ, not 4ˢ.5; and minutes assumed as 10 instead of 11, to agree with Arg. Z. 259, 69; and 265, 82.

ZONE 132. SEPTEMBER 16. P. $D_0 = -28° 55' 30''$—Continued.

REMARKS.

(133) 23. Declination 5′ 12″ discordant from Arg. Z. 336, 113; micrometer reading probably 21r.130, not 16r.130.

(133) 28. Minutes assumed as 36 instead of 37.

Sept. 21. Stars very unsteady and faint; night unfavorable.

REMARKS.

(138) 12. Transits across T.'s IV and V assumed as at $6^s.3$ and 23^s instead of 3^s and $2^s.3$.

Oct 15. Stars very unsteady; of many only glimpses would be obtained, and no observations could be made of them; mist over the river.

[a] Corr. for runs +0''.07.

REMARKS.

Oct. 27. Stars unsteady; night unfavorable; a very great change in the reading of the circle, which had been left without the usual pressure of the clamp.

(143) 1. Declination 1′ discordant from Arg. Z. 324, 114.

(143) 17. Transits discordant.

(143) 23. Transits over T.'s V and VI assumed as recorded over T.'s IV and V.

(143) 37. Transits discordant; that over T. III probably 2ˢ in error, (see Transit Z., 1847, October. 18,) and rejected.

REMARKS.

(148) 1. Minutes of transit assumed as 53, not 52.

(148) 7. Minutes of transit assumed as 4, not 5.

(148) 12. Minutes of transit assumed as 14, to agree with Arg. Z. 270, 47.

(148) 18. Declination 1′ larger than in Oeltzen.

(148) 19. Minutes of transit assumed as 42, to agree with Arg. Z. 338, 14.

(149) 4. Transits over T.'s III, IV, and V assumed to have been recorded as over T.'s II, III, and IV.

(149) 12. Transit over T. VI assumed to have been at $19^s.5$ instead of $29^s.5$.

(149) 17. Transit over T. I assumed to have been at $17^s.5$ instead of $27^s.5$.

[a] Corr. for runs $+0''.07$.

REMARKS.

(149) 34. One of the transits erroneous by 10^s; if T. VII is correct, T=$24^s.93$.

(149) 50. Either the transits over T.'s II and III or those over T.'s IV and V are erroneous by 10^s; in the latter case, T=$6^s.16$.

REMARKS.

(152) 10. Minutes assumed as 52, not 51.
(152) 18. Micrometer reading assumed as 12r.038.
(153) 4. Right ascension 9s discordant from Arg. Z. 325, 129.
(153) 8. Minutes assumed as 38, not 39.
(153) 14. Transit over T. V assumed to have been recorded as over T. IV.

ZONE 153. JANUARY 18. S. $D_o = -25° 47' 50''$—Continued.

REMARKS.

(153) 23. Transit over T. IV assumed to have been recorded as over T. III.

(154) 3. Differs 38s.5 in right ascension from Arg. Z. 323, 94, and Mer. Circle, 1849, February 16.

(154) 10. Transit over T. I assumed as recorded over T. V,

(154) 31. Differs 8s in right ascension from Arg. Z. 287, 51, and 1848, January 22, and Transit Inst., 1848, January 20.

ZONE 155. JANUARY 19. C. $D_0 = -23° 17' 30''$.

REMARKS.

(156) 2. Transit over T. VI assumed to have been recorded as over T. V.

(156) 3. Transit over T. VI assumed to have been recorded as over T. V.

(156) 18. Right ascension differs $16^s.5$ from Arg. Z. 274, 40; probably recorded over wrong thread.

(156) 27. Right ascension differs $2^s.5$ and declination 41″ from Arg. Z. 274, 62.

(156) 28. Time of transit over T. I assumed as 58^s instead of 48^s.

(156) 42. Minutes assumed as 10 instead of 11.

ZONE 156. JANUARY 20. S. $D_0 = -23° 17' 40''$—Continued.

REMARKS.

(156) 50. Micrometer reading assumed as 16r.295 instead of 15r.295.
(156) 51. Micrometer reading assumed as 41r.792 instead of 46r.792.
(156) 83. Transit over T. II assumed as 23s, not 13s.
(156) 84. Transit over T. V assumed as recorded over T. VI, and minutes assumed as 38, not 37.
(156) 87. Right ascension differs 20s.9 from Arg. Z. 362, 143; and Arg. probably wrong by 1 thread interval.
(156) 93. Transit over T. IV assumed as 55s, not 45s.
(156) 94. Declination differs 5′ from Arg. Z. 280, 146, and Z. 362, 165.

REMARKS.

(157) 42. Transit over T. II assumed as recorded over T. III; and minutes as 37, not 36.

(157) 56. Minutes assumed as 10, not 9.

(157) 57. Transit over T. V assumed as 1^s, not 51^s.

(157) 58. Transit over T. V assumed as $3^s.5$, not $58^s.5$, to agree with Arg. Z. 360, 140; and Transit Z., 1848, January 20.

(157) 65. Micrometer reading assumed as $36^r.260$, not $26^r.260$.

(157) 67. Transit at 35^s assumed to have been over T. I.

(157) 74. Transit over T. VI assumed as recorded over T. VII.

(157) 81. Differs 17^s in right ascension from Arg. Z. 290, 1.

ZONE 157. JANUARY 22. S. $D_\circ = -25° 48' 0''$—Continued.

REMARKS.

(157) 88. Minutes assumed as 40, not 39.
(157) 89. Transit over T. III assumed to have been recorded over T. IV; and as $4^s.0$, not $0^s.4$.
(158) 22. Time of transit over T. VI assumed as $20^s.8$ instead of $10^s.8$.
(158) 23. T.'s II and III of following star assumed as recorded over T.'s IV and V.
(158) 24. T. VI assumed as recorded over T. V, and combined with its T.'s II and III, as above.
(158) 25. T. VI assumed as recorded over T. V.

REMARKS.

(159) 2. Micrometer reading assumed as $30^r.311$, not $29^r.311$.

(159) 4. Transit over T. II assumed to have been recorded as over T. III, and minutes assumed as 13 instead of 12.

(159) 5. Transit over T. II assumed to have been recorded as over T. III.

(159) 14. Transit over T. I assumed as recorded over T. II.

(159) 17. Transit over T. IV probably recorded as over T. V, to agree with Arg. Z. 288, 23.

(160) 4. Micrometer reading assumed as $16^r.012$, not $15^r.012$.

(160) 11. Transit over T. IV assumed as recorded over T. III.

REMARKS.

(160) 18. Micrometer reading assumed as 21r.932, not 26r.932.

(160) 19. Micrometer reading assumed as 21r.304, not 26r.304.

(160) 27. Transit over T. III assumed to have been recorded as over T. II.

(160) 33. Minutes assumed as 29, not 28; and transit over T. V as recorded over T. VI, to agree with Arg. Z. 288, 89, and Tran., 1848, March 29.

(161) 9. Minutes of transit assumed as 39 instead of 40.

ZONE 161. MARCH 29. S. $D_0 = -25° 56' 0''$—Continued.

REMARKS.

(161) 35. Transit over T. IV assumed to have been recorded as over T. III. Minutes of transit assumed as 48.

(161) 40. Minutes assumed as 59, not 58.

(161) 46. Minutes assumed as 0.

(161) 47. Minutes assumed as 2 instead of 4.

(161) 60. Micrometer reading assumed as $12^r.760$, not $19^r.760$, to agree with Arg. Z. 292, 80; 380, 10; and Mer. Circle, 1847, May 14.

(161) 61. Revolutions of micrometer instead of horizontal thread assumed as 10.

(161) 62. Minutes assumed as 44.

ZONE 162. APRIL 1. C. $D_0 = -26° 26' 10''$.

REMARKS.

(162) 27. Minutes assumed as 52, not 53.
(162) 28. Minutes assumed as 56, not 57.
(161) 29. Time of transit over T. II assumed as 55ˢ.3 instead of 45ˢ.3.
(162) 31. Minutes of transit assumed as 58, not 59.
(162) 36. Declination differs 5′ from Arg. Z. 291, 22; probably micrometer 5′ in error.
(162) 41. Time of transit over T. IV assumed as 43ˢ instead of 53ˢ.

REMARKS.

(163) 1. Micrometer reading assumed as $10^{r}.645$, not $15^{r}.645$.

(163) 8. Transit observations discordant and recorded over T.'s IV, V, and VI instead of T.'s III, IV, and V; the record over T. IV rejected.

(163) 18. Right ascension 1^{m} discordant from Arg. Z. 291, 33; probably 23^{m}.

(163) 19. Time of transits over T. V assumed as $3^{s}.4$ instead of $5^{s}.4$.

(163) 28. Time of transit over T. VI assumed as $34^{s}.4$ instead of $31^{s}.4$.

(163) 30. Transits over T.'s V and VII assumed as at $1^{s}.2$ and $18^{s}.2$ instead of $51^{s}.2$ and $8^{s}.2$, respectively, and minutes as 48, not 49.

CORRECTIONS.

Date.		Corr. of Clock.	Hourly rate.	m	n	c	Zenith Point.	Mic. Co.
1848.	h.	s.	s.	s.	s.	s.	° ′ ″	r.

REMARKS.

(163) 40. Micrometer reading assumed as $46^r.931$, not $47^r.931$.

(163) 45. Time of transit over T. V assumed as $34^s.5$ instead of $31^s.5$.

REMARKS.

(165) 23. Time of transits over T.'s IV and V assumed as 4^s and 21^s instead of 14^s and 31^s.

(165) 36. Transits over T.'s IV and VI assumed as 58^s and 32^s, not 8^s and 42^s, and minutes as 36, not 37, and micrometer reading as $44^r.583$, not $39^r.583$, to agree with B. A. C. 4865; Arg. Z. 301, 52; and Transit Z., 1849, April 5.

(165) 37. Transits over T.'s IV and VI assumed as $58^s.3$ and $32^s.3$, not $8^s.3$ and $42^s.3$, and minutes as 36, not 37, and micrometer reading as $44^r.481$, not $39^r.481$, to agree with B. A. C. 4865; Arg. Z. 301, 52; and Transit Z., 1849, April 5.

(165) 44. Micrometer reading assumed as $21^r.762$, not $22^r.762$.

REMARKS.

(165) 67. Micrometer reading assumed as 45r.029, not 50r.029.

(166) 2. Micrometer reading assumed as 51r.998 instead of 52r.998.

(166) 9. Right ascension differs 4m from Arg. Z. 387, 100.

(166) 21. Transit over T. III assumed to have been recorded as over T. II.

(166) 27. Transit over T. III assumed as recorded over T. IV.

ZONE 166. MAY 30. S. $D_{\circ}=-24^{\circ}\ 33'\ 10''$—Continued.

REMARKS.

(167) 8. Transits over T.'s VI and VII assumed as at 41s.6 and 58s.4, not at 51s.6 and 8s.4.

(167) 9. Minutes of transit assumed as 4, not 3.

(167) 10. Right ascension differs 18s.5 from Arg. Z. 302, 69.

(167) 21. Micrometer reading assumed as 24r.643 instead of 25r.643.

Extern. therms. assumed as transposed.

Extern. therms. assumed as 64.9.

REMARKS.

(167) 36. Minutes of transit assumed as 53, not 54.

(167) 47. Right ascension differs 5^{s} from Arg. Z. 304, 44.

(167) 48. Declination differs 20″ from Arg. Z. 212, 38; 304, 45; 387, 71; and B. A. C. 5447.

(167) 68. Transit over T. IV assumed as 56^{s}, not 36^{s}.

(168) 3. Time of transit over T. V assumed as 53^{s} instead of 55^{s}.

[a] Readings of microscopes D and F assumed to be given 10″ too great.

ZONE 168. JUNE 3. C. $D_0 = -28° 18' 50''$.

REMARKS.

(170) 46. Micrometer reading assumed as 25r.050 instead of 24r.050.

(170) 47. Right ascension differs 16s from Arg. Z. 222, 22; perhaps a thread interval in error.

(170) 48. Micrometer reading assumed as 45r.842, not 43r.842.

(170) 52. Right ascension differs 49s.3 from mean of Arg. Z. 220, 72; 222, 56.

(170) 66. Transit over T. VI assumed as recorded over T. V.

REMARKS.

(170) 83. Time of transit over T. IV assumed as 52^s instead of 2^s.

(170) 84. Micrometer reading assumed as 27^r, not 26^r.

(170) 85. Micrometer reading assumed as 9^r, not 19^r.

(170) 97. Minutes of transit assumed as 51 instead of 50.

(171) 1. Minutes of transit assumed as 54 instead of 55.

(171) 5. Time of transit over T. VI assumed as 53 instead of 43.

(171) 12. Declination differs 2′ from Arg. Z. 220, 25.

(171) 17. Transit over T. V assumed to have been recorded as over T. VI.

(171) 21. Minutes assumed as 47, not 49.

REMARKS.

(172) 1. Micrometer reading assumed as $55^r.959$, not $56^r.959$.

(172) 15. Transits over T.'s IV and VI assumed as at $20^s.2$ and $45^s.3$ respectively, on the supposition that two components were observed.

(172) 17. Right ascension differs $9^s.5$ from Arg. Z. 373, 54.

(172) 28. Declination in error about 40″.

(172) 41. Transits over T.'s III and V assumed as recorded over T.'s IV and VI, and minutes as 2, not 1.

Therm. readings assumed to be transposed.

ZONE 173. JUNE 16. S. $D_0 = -28° 18' 30''$.

REMARKS.

(173) 1. Transit over T. IV assumed as recorded over T. III: and micrometer reading as $7^r.920$, not $8^r.920$, to agree with B. A. C. 5297; M. C. Z., 1846, May 4; M. C. Z., 1847, April 25.

(173) 2. Transit over T. IV assumed to have been recorded as over T. V; and minutes as 53, not 52.

(173) 16. Transit over T. V assumed as at $0^s.8$ instead of $50^s.8$.

(173) 26. Transit over T. II assumed as $24^s.5$, not $14^s.5$.

(173) 28. Minutes assumed as 45 instead of 46.

(173) 31. Time of transit over T. VI assumed as 19^s instead of 29^s.

(173) 34. Minutes assumed as 56, not 55.

ZONE 174. JUNE 20. C. $D_0 = -23° 18' 0''$.

CORRECTIONS.

Date.		Corr. of Clock.	Hourly rate.	m	n	c	Zenith Point.	Mic. Co.
1848.	h.	s.	s.	s.	s.	s.	° ′ ″	r.

REMARKS.

(175) 29. Micrometer reading assumed as $25^r.957$, not $24^r.957$.

(175) 33. Right ascension differs 1^m from Arg. Z. 387, 49; should probably be $16^h\ 0^m$.

[(175) 59. 16^s after wire VII.]

REMARKS.

(175) 85. Declination differs 20′ from Arg. Arg. Z. 224, 33, and 307, 44; probably another star.

(176) 2. Transit over T. IV assumed to have been recorded as over T. V.

REMARKS.

(176) 24. Transits over T.'s II and IV assumed as recorded over T.'s III and V.

(176) 25. Micrometer reading assumed as 21r.601, not 36r.601, to agree with Arg. Z. 214, 95; 217, 29; 306, 34; 388, 126; and Transit Z., 1846, July 9.

(167) 28. Transit over T. III assumed as at 6s.0 instead of 56s.

(176) 53. Micrometer reading assumed as 42r.188, not 47r.188.

(176) 55. Micrometer reading assumed as 44r.889, not 39r.889.

(176) 59. Micrometer reading assumed as 18r.102, not 17r.102.

(176) 60. Transit over T. III assumed to have been recorded as over T. II.

(176) 62. Time of transit over T. IV assumed as 56s.0 instead of 46s.

(176) 68. Micrometer reading assumed as 38r.908, not 37r.908.

REMARKS.

(179) 6. Micrometer reading assumed as $40^r.967$, not $41^r.967$.

(179) 10. Transits over T.'s IV and V assumed as recorded over T.'s V and VI.

(180) 6. Micrometer reading assumed as $31^r.078$, not $30^r.078$.

(180) 27. Time of transit over T. II assumed as $4^s.5$ instead of $14^s.5$.

ZONE 181. JULY 18. C. $D_0 = -22° 2' 50''$.

REMARKS.

(180) 105. Declination differs 1′ from Arg. Z. 238, 43.

(180) 119. Micrometer reading assumed as 38r.902 instead of 39r.902.

(181) 6. Micrometer reading assumed as 28r.353.

(181) 9. Minutes assumed as 58, not 57, to agree with Arg. Z. 224, 39; and 307, 52.

(181) 12. Micrometer reading assumed as 10r.680, not 5r.680.

[a] Corr. for runs +0″.07.

REMARKS.

(181) 27. Micrometer reading assumed as $36^r.058$, and minutes of transit as 22 instead of 23, to correspond with Arg. Z. 307, 96.

(181) 37. Minutes of transit assumed as 42, not 43.

(181) 41. Transit over T. IV assumed as recorded over T. III.

(181) 54. Right ascension differs 13^s from Arg. Z. 238, 15; and Mural Z., 1848, July 18, and is wrong.

(181) 70. Transit over T. V assumed as $1^s.0$ instead of $0^s.1$, to agree with Transit Z., 1848, August 7.

ZONE 181. JULY 19. S. $D_0 = -21° 25' 0''$—Continued.

REMARKS.

(181) 78. Micrometer reading assumed as $24^r.770$, not $19^r.770$.

(181) 80. Time of transit over T. II assumed as 42^s instead of 32^s.

(181) 88. Micrometer reading assumed as $32^r.090$ instead of $31^r.090$.

(181) 103. Right ascension differs from Arg. Z. 237, $5 = 10^s.4$.

ZONE 181. JULY 19. S. $D_\circ = -21° 25' 0''$—Continued.

REMARKS.

(182) 44. Time of transit over T. VI assumed as 0ˢ.8 instead of 8ˢ.

(182) 52. Transits over T.'s V and VI assumed as recorded over T.'s IV and V.

(182) 53. Transits over T.'s IV and V assumed as recorded over T.'s V and VI.

(182) 60. Transit over T. III assumed to have been recorded as over T. IV.

(183) 2. Time of transits over T.'s III, IV, V, and VI assumed as 44ˢ.2, 1ˢ.3, 18ˢ, and 35ˢ instead of 34ˢ.2, 51ˢ.3, 8ˢ, and 25ˢ; and minutes as 15, not 14.

(183) 11. Time of transit over T. V assumed as 42ˢ.3 instead of 52ˢ.3.

ZONE 183. JULY 20. C. $D_0 = -23° 17' 50''$—Continued.

REMARKS.

(183) 19. Time of transit over T. VI assumed as $17^s.5$ instead of $47^s.5$.

(183) 28. Transits over T.'s V and VI assumed as 37^s and $53^s.5$, not 27^s and $43^s.5$.

(184) 4. Transits over T.'s II, III, IV, and V assumed as recorded over T.'s I, II, III, and IV, and minutes 19, not 20.

(184) 5. Transit over T. II assumed to have been recorded as over T. III.

(184) 7. Minutes assumed as 24, not 25.

(184) 10. Transit over T. III assumed as recorded over T. II.

(184) 13. Right ascension differs $18^s.2$ from Arg. Z. 243, 105; probably 1 thread interval in error.

(184) 16. Micrometer reading assumed as $49^r.552$, to agree with Mer. Circle, 1848, September 1, and Transit, July 24.

REMARKS.

(186) 22. Mic. reading assumed as 44r.919, not 45r.919, to agree with Arg. Z. 237, 38, and 247, 106.
(186) 23. Min. of transit assumed as 4, not 5.
(186) 32. Time of transit over T. V assumed as 6s.7 instead of 0s.7.
(187) 2. Right ascension differs 17s.2 from Arg. Z. 227, 64; probably 1 thread interval in error.
(187) 3. Minutes assumed as 32, not 33, to agree with Arg. Z. 227, 67, and 310, 68.
(187) 4. Transit over T. V assumed as recorded over T. VI, and minutes as 33, not 34.
(187) 6. Transit over T. VI assumed as recorded over T. VII.
(187) 15. Transits over T.'s IV and V ass'd as recorded over T.'s V and VI.
(187) 17. Right ascension differs 17s from Arg. Z. 224, 114; probably 1 thread interval in error.
(187) 18. Right ascension differs 28s.3 from Arg. Z. 227, 99.

REMARKS.

(187) 22. Transit over T. III ass'd to have been recorded as over T, II.

(187) 30. Right ascension differs $16^s.6$ from Arg. Z. 310, 148; probably 1 thread interval in error.

(187) 33. Transit over T. IV assumed as recorded over T. V.

(187) 34. Transit over T. V ass'd as rec'ded over T. VI to agree with Arg. Z. 227, 133; 238, 32; and 310, 155.

(187) 39. Transits over T.'s IV and V assumed as recorded over T.'s V and VI.

(187) 41. Transit over T. V assumed as recorded over T. VI.

(187) 42. Transit over T. IV assumed as recorded over T. V.

(187) 46. Transit over T. IV assumed as recorded over T. V.

(187) 48. Right ascension differs $17^s.7$ from Arg. Z. 243, 36; probably 1 thread interval in error.

(187) 49. Transit over T. III ass'd to have been recorded as over T. II.

REMARKS.

(187) 81. Minutes of transit assumed as 32.

(187) 83. Transit over T. IV ass'd to have been at $55^s.5$ instead of $35^s.5$.

(187) 90. Right ascension differs $16^s.1$ from Arg. Z. 255, 75; perhaps 1 thread interval in error.

(188) 1. Micrometer reading assumed as $20^r.683$, not $15^r.683$.

(188) 14. Time of transit over T. II assumed as 57^s. instead of 37^s.

(188) 15. Minutes assumed as 24, not 23, to agree with Arg. Z. 310, 165.

Extern. therm. assumed as 72°.8.

Zone 188. August 14. S. $D_0 = -19° 32' 30''$—Continued.

REMARKS.

(191) 1. Right ascension differs 2ˢ.5 from Arg. Z. 251, 19; wrong.

(191) 15. Micrometer reading assumed as 18ʳ.640, not 13ʳ.640.

(191) 17. Transits over T.'s III, IV, and V assumed as 37ˢ, 54ˢ, and 11ˢ, to agree with Arg. Z. 242, 721, and 251, 74; and Mur. October 14, 1848.

(192) 20. Declination differs 5′ 19″ from Arg. Z. 311, 35; micrometer probably 5ʳ in error.

REMARKS.

(194) 1. Perhaps micrometer 2^r in error. (See Tables $\Delta\alpha$ and $\Delta\delta$.)

(195) 12. Minutes of transit assumed as 24 instead of 25. Time of transit over T. III assumed as 53^s instead of 43^s.

(195) 15. Micrometer reading assumed as $31^r.910$, instead of $32^r.910$

*Hour assumed as 20^h instead of 23^h, and degrees of circle reading as 70° instead of 60°.

ZONE 195. AUGUST 30. S. $D_0 = -23° 17' 50''$—Continued.

1848.	h.	s.	s.	s.	s.	s.	° ′ ″	r.

REMARKS.

(195) 23. Micrometer reading assumed as $45^r.000$, not $35^r.000$.

(196) 6. Time of transit over T. II assumed as $49^s.5$ instead of $39^s.5$.

(196) 7. Time of transit over T. VI assumed as 7^s instead of 57^s.

REMARKS.

(200) 50. Micrometer reading assumed as $46^r.650$, not $41^r.650$.

(200) 58. Declination differs 25″ from Arg. Z. 243, 111; perhaps micrometer reading should be $21^r.992$, not $21^r.592$.

(200) 67. Transit over T. III assumed to be recorded as over T. IV.

(200) 68. Micrometer reading assumed as $36^r.102$ instead of $35^r.102$.

(200) 76. Micrometer reading assumed as $40^r.758$ instead of $41^r.758$.

(200) 78. Transits over T.'s III, IV, and V assumed as recorded over T.'s II, III, and IV.

(200) 90. Micrometer reading assumed as $38^r.345$, not $33^r.345$.

[a]Assumed as 68.3.

ZONE 201. SEPTEMBER 1. S. $D_0 = -20° 10' 0''$.

REMARKS.

(201) 25. Time of transit over T. IV assumed as 52^s instead of 22^s, and minutes as 13, not 14.

(201) 28. Transits over T.'s III, IV, and V assumed as recorded over T.'s II, III, and IV.

(201) 34. Declination differs 1′ from Arg. Z.

(201) 35. Transit over T. VI assumed to have been recorded as over T. V.

[a]The second set of double readings given for $23^h\ 10^m$ is assumed to belong to $1^h\ 0^m$, making the mean for the former hour 27.16 and for the latter 26.03.

ZONE 202. SEPTEMBER 2. C. $D_0 = -23° 55' 10''$.

REMARKS.

(202) 8. Transit over T. II assumed to have been recorded as over T. III.

(202) 14. Time of transit over T. IV assumed as 55ˢ.2 instead of 45ˢ.2.

(202) 40. Transits over T.'s IV and VI assumed as recorded over T.'s V and VII.

ZONE 202. SEPTEMBER 2. C. $D_\circ$ = 23° 55′ 10″—Continued.

REMARKS.

(204) 7. Minutes assumed as 25, not 26.

(204) 14. Micrometer reading assumed as $34^r.188$, not $34^r.688$.

(204) 15. Micrometer reading assumed as $38^r.848$, not $43^r.848$.

(204) 16. Time of transit over T. VI assumed as $39^s.2$ instead of $29^s.2$.

(204) 19. Declination differs 1′ from Arg. Z. 252, 81.

(204) 22. Minutes assumed as 57, not 56, and micrometer reading as $10^r.871$, not $10^r.371$.

(204) 26. Declination differs 1′ from Arg. Z. 252, 96.

[(204) 5. Precedes 4.2^s or 3^s.]

REMARKS.

(204) 39. Micrometer reading assumed as 54ʳ.602, not 56ʳ.602.

(204) 40. Time of transit over T. VI assumed as 37ˢ instead of 47ˢ.

(204) 41. Time of transit over T. VI assumed as 38ˢ.5 instead of 48ˢ.5.

(204) 42. Micrometer reading assumed as 42ʳ.041, not 41ʳ.041.

(204) 43. Minutes of transit assumed as 31 instead of 30.

(204) 49. Declination differs 1′ from Arg. Arg. Z. 244, 95.

(204) 62. Transits over T.'s IV, V, and VI assumed to have been recorded as over T.'s III, IV, and V, and minutes as 28, not 29.

ZONE 205. OCTOBER 7. C. $D_0 = -16^\circ\ 24'\ 50''$.

REMARKS.

(206) 71. Right ascension differs 10ˢ and declination 20′ from Arg. Z. 331, 34.

(206) 76. Transit over T. IV assumed as recorded over T. V.

(206) 101. Transit over T. IV assumed as recorded over T. III.

(206) 112. Right ascension differs 1ᵐ from Arg. Z. 318, 35.

ZONE 206. OCTOBER 10. S. $D_{\circ} = -17° 39' 40''$—Continued.

REMARKS.

(207) 27. Transits over T.'s III and IV ass'd as recorded over T.'s IV and V.

(207) 28. Transit over T. II assumed to have been recorded as over T. III, and minutes as 7, not 6.

(207) 30. Micrometer reading assumed as $36^r.398$, not $26^r.398$.

(207) 32. Transit over T. V assumed as recorded over T. VI; T. II discordant and rejected.

(207) 34. Transit over T. VI assumed at $1^s.3$ instead of over T. V at 13^s.

(207) 41. Transits assumed at $31^s.2$ and $3^s.8$ instead of $51^s.2$ and 38^s, respectively.

(207) 50. Time of transit over T. III assumed as 25^s instead of 35^s.

(207) 51. Trans. ass'd as recorded over T.'s V and VI, as originally rec'ded, to agree with Arg. Z. 256, 54.

(207) 52. Transit over T. V ass'd to have been recorded as over T. VI.

(207) 56. Minutes assumed as 49, not 50; and transits over T.'s II and III as 32^s and $48^s.3$, not 42^s and $58^s.3$.

REMARKS.

(207) 75. Right ascension differs 12^s from Arg. Z. 256, 107; and Mer. Cir., 1848, October 14.

(208) 4. Micrometer reading assumed as $22^r.516$, not $17^r.516$.

(208) 9. Transit over T. II assumed as recorded over T. III.

(208) 10. Micrometer reading assumed as $14^r.425$, not $19^r.425$.

[(207) 74. Precedes 75. 6^s.]

REMARKS.

(208) 38. Time of transit over T. II assumed as 23^s instead of 33^s.

(208) 64. Micrometer reading assumed as $38^r.960$ instead of $39^r.960$.

(208) 72. Micrometer reading assumed as $23^r.820$, not $18^r.820$.

(208) 74. Micrometer reading assumed as $27^r.932$, not $17^r.932$.

REMARKS.

(208) 94. Time of transit over T. IV assumed as 5^s instead of $0^s.5$.

(208) 99. Micrometer reading assumed as $50^r.620$ instead of $51^r.620$.

External thermometer assumed as 31°.9.

ZONE 209. NOVEMBER 28. C. $D_0 = -27° 3' 0''$—Continued.

REMARKS.

(211) 8. Micrometer reading assumed as $34^r.288$ instead of $33^r.288$.

(211) 16. Micrometer reading assumed as $35^r.616$ instead of $25^r.616$.

(211) 21. Right ascension differs $20^s.8$ from Arg. Z. 269, 24.

(211) 44. Micrometer reading assumed as $50^r.846$, not $49^r.846$.

(211) 49. Transit over T. VI assumed to have been recorded as over T. V.

[(211 42. Precedes 41. 2^s.]

REMARKS.

(211) 50. Transits over T.'s V and VI assumed to have been recorded as over T.'s IV and V, respectively; and minutes as 35, not 36.

(211) 65. Declination differs 2′ from Arg. Z. 317, 1; micrometer reading probably should be $41^r.362$.

[(211) 56. ? $+1^s$.]

REMARKS.

(212) 23. Time of transit over T. IV assumed as 3s instead of 0s.3.

(213) 25. Declination differs 1m from Arg. Z. 322, 45.

(213) 39. Right ascension differs 48s.4 from Arg. Z. 322, 75.

REMARKS.

(213) 60. Transits over T.'s III and IV assumed as $9^s.2$ and $27^s.2$, not $59^s.2$ and $17^s.2$, and minutes as 58, not 59, to agree with Arg. Z. 350, 1, and Mural October 18, 1847.

(213) 63. Declination differs 1′ from Arg. Z. 322, 117, and 350, 6; micrometer reading perhaps to be assumed as $42^r.062$.

REMARKS.

(219) 11. Declination differs 9′ 37″ from Arg. Z. 274, 129, and Transit Z. January 22, 1848.

(219) 17. Declination differs 24″ from Arg. Z. 274, 137, and Transit Z. January 22, 1848; micrometer reading perhaps 39.668.

*Minutes of circle reading assumed as 34 instead of 39.

[(219) 10. Doubtful 10s.]

REMARKS.

(220) 4. Transit over T. II assumed as at 39^s instead of 49^s.

(220) 5. Transit over T. III assumed as at 55^s instead of 45^s.

(220) 31. Transits 1^s discordant.

(220) 45. Micrometer reading assumed as $20^r.900$, not $25^r.900$, to agree with Arg. Z. 350, 149; 353, 33; and 357, 89.

ZONE 220. FEBRUARY 9. S. $D_{\circ} = -28° 19' 0''$—Continued.

REMARKS.

(220) 56. Micrometer reading assumed as 44r.450, not 49r.450.

(220) 65. Minutes assumed as 16, not 17.

(220) 69. Declination differs 10′ 28″ from Arg. Z. 357, 141; micrometer reading probably 34r.738.

(221) 2. Micrometer reading assumed as 50r.813, not 51r.813.

(221) 8. Transits discordant; T. VI rejected.

(221) 15. Micrometer reading assumed as 40r.679, not 45r.679, to agree with Arg. Z. 352, 62, and 360, 231.

(222) 10. Transit over T. VI assumed to have been recorded as over T. V.

(222) 22. Micrometer reading assumed as $44^r.931$, not $49^r.931$.

(222) 37. Right ascension differs 1^m from Arg. Z. 351, 47.

(222) 41. Time of transit over T. IV assumed as at $53^s.2$ instead of $43^s.2$.

[(222) 16. Precedes 15. 10^s.]

[a] Barom. assumed as 30.020; at. therm., 38.5.

ZONE 223. FEBRUARY 13. C. $D_0 = -32° 4' 50''$.

REMARKS.

(228) 16. Declination differs 1′ from Arg. Z. 368, 44.

(228) 18. Transit over T. II assumed as recorded over T. I.

(228) 19. Right ascension differs 10^s from Arg. Z. 368, 48.

(228) 32. Micrometer reading assumed as $54^r.149$.

(228) 35. Transits 2^s discordant.

(229) 2. Time of transit over T. II assumed as $15^s.5$ instead of $10^s.5$.

(229) 5. Time of transit over T. IV assumed as $58^s.5$ instead of $8^s.5$.

(229) 7. Micrometer reading assumed as $34^r.222$, not $24^r.222$.

ZONE 229. FEBRUARY 19. C. $D_0 = -28° 54' 20''$—Continued.

REMARKS.

(232) 47. Transits over T.'s III and V assumed as $0^s.3$ and 57^s, not $20^s.3$ and 7^s, to agree with Transit Z., March 7, 1849.

(232) 84. The only means of harmonizing these transits is to suppose transit over T. II recorded over T. III, and as $34^s.4$, not $14^s.4$; and transit over T. VI as $50^s.3$ and not $20^s.3$.

(232) 85. Time of transit over T. VI assumed as $2^s.4$ instead of $22^s.4$.

ZONE 232. MARCH 7. C. $D_0 = -34° 35' 0''$—Continued.

REMARKS.

(237) 5. Transit over T. IV rejected; declination differs 1′ from Mer. Circle Z. March 19, 1849.

(237) 20. Declination differs about 15″ from Mer. Circle Z. March 19, 1849, and Transit Z. March 12, 1849.

(237) 48. Time of transit over T. V assumed as 28^s instead of 38^s.

ZONE 237. MARCH 22. S. $D_0 = -35° 10' 20''$—Continued.

REMARKS.

(243) 95. Right ascension differs 4s.4 from Mural Z. March 16, 1849.

(243) 109. Minutes assumed as 40, not 39.

ZONE 243. APRIL 2. S. $D_\circ = -34° 35' 20''$—Continued.

REMARKS.

(248) 21. Transit over T. VI assumed to have been recorded as over T. V.

(248) 31. Micrometer reading assumed as $45^r.359$ instead of $46^r.359$.

(248) 35. Clouds suspected.

(248) 36. Mist obscuring small stars, stopped.

(248) 37. Apparently clear; perhaps a little mist remaining.

ZONE 248. APRIL 12. C. $D_0 = -23° 56' 10''$—Continued.

REMARKS.

(251) 3. Right ascension 1^m different from Arg. Z. 288, 123.

(251) 4. Transit over T. IV assumed as recorded over T. III, and minutes as 53, not 54.

(251) 12. Right ascension differs 3^s from Arg. Z. 281, 115; 293, 7, and Mer. Cir. Z., April 11, 1849. Transit over T. II probably $8^s.6$.

(251) 26. Transit over T. V assumed as recorded over T. IV.

Ex. therm. assumed as 42.9.

ZONE 251. APRIL 20. S. $D_0 = -24° 34' 0''$—Continued.

REMARKS.

(254) 12. Right ascension differs 1^m from Arg. Z. 208, 99.

(254) 20. Minutes of transit assumed as 57, not 58.

(254) 23. Micrometer reading assumed as $21^r.468$ instead of $20^r.468$.

(254) 25. Transit over T. III assumed as at $48^s.5$ instead of $58^s.5$.

(254) 26. Right ascension differs 1^m from Arg. Z. 211, 16; 305, 12; minutes probably 6.

(254) 30. Micrometer reading assumed as $47^r.952$, not $42^r.952$.

(254) 31. Micrometer reading assumed as $48^r.170$, not $43^r.170$.

(254) 34. Minutes assumed as 26, not 27.

(254) 37. Minutes of transit assumed as 32, not 33.

(254) 41. Minutes assumed as 39, not 40.

(254) 48. Assumed transit over T. III at $36^s.2$.

REMARKS.

(255) 82. Minutes assumed as 42, not 43.
(255) 89. Minutes assumed as 48, not 49, to agree with Arg. Z. 392, 19; 393, 12.
(255) 98. Time of transit over T. V assumed as $45^s.2$.
(256) 2. Right ascension differs 16^s from Arg. Z. 209, 87; perhaps one thread interval in error.
(256) 6. Transit over T. V assumed as recorded over T. IV.
(256) 9. Transit over T. V assumed as recorded over T. IV, and minutes as 1, not 2.
(256) 10. Transit over T. V assumed as recorded over T. IV, and minutes as 2, not 3.
(256) 23. Declination differs 16″ from Arg. Z. 213, 46; 302, 3; micrometer reading, perhaps, $10^r.532$.
(256) 26. Micrometer reading assumed as $47^r.969$, not $42^r.969$.
[(*255) From 84 to 99, inclusive, under Micrometer, add I to IV, IV, V, etc.]

(256) 47. Micrometer reading assumed as $17^r.132$, not $7^r.132$.
(257) 5. Minutes assumed as 10, not 11.
(257) 7. Minutes assumed as 23, not 24.
(257) 12. Right ascension differs 1^m from Arg. Z. 211, 51; minutes probably 45, not 46.
(257) 16. Minutes assumed as 54, not 55.

*Minutes of circle reading assumed as 33 instead of 32.

REMARKS.

(257) 26. Transits discordant. Assumed observation on T. I as $20^s.2$ instead of $26^s.2$, when R. A. differs 20^s from Arg. Z. 211, 78.

(257) 27. Minutes assumed as 9, not 10; and mic. reading as $42^r.187$, not $41^r.187$, to agree with Arg. Z.

(257) 28. Minutes assumed as 9, not 10.

(257) 36. R. A. differs 1^m from Arg. Z. 213, 95; minutes probably 19, not 20.

(257) 42. Minutes assumed as 31, not 32.

(257) 50. Minutes assumed as 45, not 46.

(257) 53. Minutes assumed as 50, not 51.

(257) 57. Minutes assumed as 55, not 56.

(257) 58. Transits over T.'s I and II ass'd as $57^s.3$ and $13^s.8$, not $47^s.3$ and $3^s.8$.

(257) 59. Transit over T. V perhaps belongs to preceding reading; and declination, with 1 mic. rev. in error, to Arg. Z. 310, 7.

(257) 61. R. A. assumed as 17^h 59^m.

(257) 65. R. A. differs 1^m from Arg. Z. 310, 19; minutes probably 3.

(257) 67. Minutes ass'd as 5, not 6, to agree with Arg. Z. 307, 66; 310, 22.

REMARKS.

(257) 75. Minutes assumed as 14.
(257) 79. Minutes assumed as 20, not 21.
(257) 82. Right ascension differs 36ˢ from Arg. Z. 310, 56.
(257) 85. Right ascension differs 1ᵐ from Arg. Z. 310, 61; minutes probably 27, not 28.
(257) 90. Right ascension differs 1ᵐ from Arg. Z. 310, 67; and minutes probably 31, not 32.
(257) 91. Transit over T. V assumed to have been recorded over T. IV.
(257) 99. Minutes assumed as 38, not 39.
(258) 3. Transit over T. IV assumed to have been recorded over T. VI.
(258) 5. Micrometer reading assumed as 24ʳ.714, not 20ʳ.714, to agree with Arg. Z. 211, 25, and 305, 25.
(258) 13. Right ascension differs 17ˢ from Arg. Z. 300, 53; transit over T. II perhaps recorded over T. III.

[a] Used as 79°.2.

REMARKS.

(258) 41. Declination differs 1' from Arg. Z. 211, 107.

(258) 56. Transit over T. III assumed as recorded over T. V; and minutes as 56, not 57.

(258) 60. Time of transit over T. III assumed as 32ˢ.3 instead of 28ˢ.3.

(258) 63. Transit over T. III assumed as recorded over T. II, to agree with Arg. Z. 218, 50; 219, 42; 227, 21; and 391, 129.

REMARKS.

(258) 74. Declination differs 10ˢ from Arg. Z. 227, 51; micrometer reading perhaps $39^r.752$, not $39^r.852$.

(258) 75. Time of transit over T. V assumed as 42^s instead of 32^s.

(258) 105. Declination differs 5′ 15″ from Arg. Z. 227, 117; micrometer reading probably $20^r.082$, not $15^r.082$.

(258) 109. Transit over T. II assumed as $48^s.3$, not $46^s.3$, to agree with Meridian Circle Z., August 25, 1849, and Transit August 14, 1848.

(258) 111. Micrometer reading assumed as $23^r.290$, not $26^r.290$.

REMARKS.

(259) 1. Right ascen. differs 1^m from Arg. Z. 385, 42; min. probably 2.

(259) 2. Right ascension differs 1^m from Arg. Z. 208, 41; minutes perhaps 3, and transit over T. V 25^s, not 28^s.

(259) 5. Right ascen. differs 1^m from Arg. Z. 208, 52; min. probably 9.

(259) 8. Assumed the transits over T.'s IV and V as 34^s.1 and 50^s.6 instead of 14^s.1 and 30^s.6, respectively.

(259) 11. Minutes assumed as 21, not 22, to agree with Arg. Z. 208, 66; 385, 69.

(259) 16. Assumed the minutes as 30 instead of 31.

(259) 22. Right ascension differs 1^m from Arg. Z. 208, 99.

(259) 25. Minutes assumed as 48, not 49.

(259) 27. Declination differs 10′ from Arg. Z. 208, 84.

(259) 31. Right ascen. differs 1^m from Arg. Z. 209, 94; min. probably 56.

REMARKS.

(259) 39. The number (25) of micrometer revolutions deduced from comparison with zone of June 20.
(259) 41. Minutes assumed as 10, not 11.
(259) 43. Time of transit over T. V assumed as $57^s.0$ instead of $59^s.0$.
(260) 1. Minutes assumed as 57 instead of 58.
(260) 9. Minutes assumed as 9, not 10.
(260) 16. Micrometer reading assumed as $16^r.808$, not $11^r.808$.
(260) 17. Micrometer reading assumed as $35^r.664$ instead of $36^r.664$.
(260) 30. Right ascension differs $1^m\ 3^s$ from Arg. Z. 219, 7; minutes perhaps 40, not 41; and transit over T. V 24^s, not 27^s.
(260) 34. Minutes assumed as 44, not 45.

*The mean 61″.30 is corrected by −0″.25 in order to reduce the mean of five microscopes to the mean of six.

REMARKS.

(261) 29. Minutes assumed as 32, not 33.
(261) 32. Right ascension differs 10^s from Arg. Z. 221, 119.
(261) 39. Minutes assumed as 42, not 43.
(261) 42. Minutes assumed as 45, not 46.
(261) 44. Minutes assumed as 46, not 47.
(261) 47. Minutes assumed as 53, not 54.
(262) 2. Transit observations discordant by 2^s; their mean doubtless 1^s in error.
(262) 6. Time of transit over T. I assumed as $55^s.6$ instead of $5^s.6$.

REMARKS.

(264) 6. Transit over T. III assumed as recorded over T. IV.
(264) 9. Minutes assumed as 2, not 3.
(264) 13. Minutes assumed as 5, not 6.
(264) 18. Right ascension differs 1^m from Arg. Z. 213, 85; minutes probably 11, not 12.
(264) 19. Transit over T. V assumed as recorded over T. IV.
(264) 20. Transit over T. V assumed as recorded over T. IV, to agree with Arg. Z. 393, 50, and minutes as 12, not 13.
(265) 3. Minutes of transit assumed as 5, not 6.
(265) 14. Minutes assumed as 21, not 22.
(265) 17. Transits discordant by 2^s; their mean probably 1^s in error.
(265) 18. Minutes assumed as 25, not 26.

REMARKS.

(266) 17. Right ascension differs 1^m from B. A. C. 5908, depending only on Lacaille 6108.

(267) 1. Transit over T. V assumed to have been at $59^s.5$ instead of $9^s.5$.

(267) 27. Right ascension assumed as $17^h\ 59^m$, to agree with Arg. Z. 224, 44; 307, 56.
